Abstract

The expression of displeasure on a consumer’s behalf towards an organization, product, or event is denoted via the speech act known as complaint. Customers typically post reviews on retail websites and various social media platforms about the products or services they purchase, and the reviews may include complaints about the products or services. Automatic detection of consumers’ complaints about items or services they buy can be critical for organizations and online merchants since they can use this insight to meet the customers’ requirements, including handling and addressing the complaints. Previous studies on Complaint Identification (CI) are limited to text. Images posted with the reviews can provide cues to identify complaints better, thus emphasizing the importance of incorporating multi-modal inputs into the process. Furthermore, the customer’s emotional state significantly impacts the complaint expression since emotions generally influence any speech act. As a result, the impact of emotion and sentiment on automatic complaint identification must also be investigated. One of the major contributions of this work is the creation of a new dataset- Complaint, Emotion, and Sentiment Annotated Multi-modal Amazon Reviews Dataset (CESAMARD), a collection of opinionated texts (reviews) and images of the products posted on the website of the retail giant Amazon. We present an attention-based multi-modal, adversarial multi-task deep neural network model for complaint detection to demonstrate the utility of the multi-modal dataset. Experimental results indicate that the multi-modality and multi-tasking complaint identification outperforms uni-modal and single-task variants.

Introduction

Nowadays, social media platforms and online e-commerce websites provide users the freedom to express their opinions and observations towards a product, an organization, or an event. Customers who plan to buy a product often base their decision on customer reviews (Preotiuc-Pietro, Gaman, and Aletras 2019). As a result, commercial and retail firms consider product reviews as a significant source of knowledge, which they can use to design their advertising strategies, and also aid in resolving any product-related concerns. This could also benefit customer by providing recommendations on the quality of goods or services that they intend to buy. Identifying complaint texts in natural language is critical for developers of downstream applications such as chatbots (Lailiyah, Sumeno, and Purnama 2017), commercial organizations or counsels to strengthen their customer service capabilities by identifying and resolving product-related issues (Coussement and Van den Poel 2008).

The emotional state and sentiment of an individual have a significant impact on the intended content (Lewis, Haviland-Jones, and Barrett 2010). Generally, sentiment and emotion are seen as two different tasks (Majumder et al. 2019; Soleymani et al. 2017; Do et al. 2019) but in reality, sentiment and emotion are closely associated. However, the process of emotion recognition is far more subtle and fine-grained in terms of its analysis than sentiment classification (Kumar et al. 2019). Emotion, together with the sentiment, offers a greater insight into the customer’s frame of mind. For example, a question or an inquiry would only have neutral sentiment, but emotion could be anger or anticipation. The correlation between emotion and sentiment motivates us to consider customers’ sentiment and emotion while analyzing complaints. We learn the tasks of complaint identification, emotion recognition, and sentiment classification in a multi-task setting to further examine the relationship between complaint, emotion, and sentiment.

Due to technological advancements, people can now share their views or opinions in multiple modalities. The fact that nearly every content sharing and e-commerce platform allows users to accompany their review with multiple media forms and every mobile phone has that ability exemplifies the superiority of a multi-modal form of communication in terms of ease of conveying and understanding information.

The key contributions of our proposed work are:

- We curate a new dataset, CESAMARD, for aiding multimodal complaint identification research with good quality annotations, including emotion and sentiment classes.
- We highlight the relevance of using multi-modal sources of information and the sentiment and emotion class of the review while identifying complaints through examples.
- We propose a dual attention-based multi-task adversarial learning framework for multi-modal complaint, emotion, and sentiment analysis. The dual attention mechanism utilizes inter-segment inter-modal attention and
contextual inter-modal attention. Complaint Identification (CI) is the primary task in our multi-task framework, whereas Emotion Recognition (ER) and Sentiment Analysis (SA) are considered supplementary (i.e., auxiliary) tasks. Multi-modal and multi-task CI surpasses unimodal and single-task CI considerably.

- We present the state-of-the-art for automatically identifying complaints in the multi-modal scenario.

Related Work

Almost all e-commerce websites allow customers to publicly voice their opinions and thoughts concerning products on their websites and social media channels. E-commerce corporations and online retailers want to detect complaints based on product reviews for their profit. Due to the plethora of information available online, companies and retailers find it challenging to identify complaints and address the issues directly. Additionally, detecting complaints on social media entails detecting complaints from unstructured and noisy text snippets with character limitations, usage of random abbreviations, ironical expressions, allegations (Pawar et al. 2015), making it a laborious and tedious task. According to an analysis of relevant literature, a multi-modal approach to complaint detection, as opposed to text-based classification, is a new approach. In this context, text-based complaints have been previously analyzed based on semi-supervised strategies, different domains, degree of urgency, and feedback likelihood (Preotiuc-Pietro, Gaman, and Aletras 2019; Singh et al. 2021; Tjandra, Warsito, and Sugiono 2015; Yang et al. 2019), (Jin and Aletras 2020).

Recent studies (Qureshi et al. 2019; Akhtar, Ekbal, and Cambria 2020; Ghosh, Ekbal, and Bhattacharyya 2021) have demonstrated the effectiveness of multi-task systems by learning numerous correlated tasks simultaneously. In the area of emotion and sentiment recognition in human conversations, multi-modality has become a popular research area (Poria et al. 2018; Akhtar et al. 2019; Chauhan et al. 2020). Although multi-modal information sources (e.g., images in addition to text) could provide more information in identifying complaints, this has not been investigated to date, with one of the main reasons being a lack of multi-modal datasets.

In this work, we initially collect the publicly posted reviews and images posted by customers from the Amazon India website and then manually annotate each review with the complaint, emotion, and sentiment labels. Subsequently, we propose a deep learning-based framework with dual attention mechanisms to leverage information from images as well as complaint texts for identifying complaints in a multi-modal multi-task framework. To the best of our knowledge, this is the first attempt to solve the multi-modal complaint detection problem in a deep multi-task framework.

Complaint, Emotion, and Sentiment Annotated Multi-modal Amazon Reviews Dataset (CESAMARD)

The existing complaint datasets (Preotiuc-Pietro, Gaman, and Aletras 2019; Singh et al. 2020) deal with text-based complaints only and do not consider the sentiment and emotion classes of the complaints. For building a multi-modal multi-task model, we curate a multi-modal complaint corpus which has been labeled with emotion and sentiment classes, one of the contributions of our current work. Here, we discuss the details of the CESAMARD dataset.

Data Collection

To the best of our knowledge, there is no existing (freely available) annotated complaint dataset that comprises customer-posted reviews and images of the items purchased. To build an annotated multi-modal dataset, we initially gathered reviews from Amazon India’s website. To collect the product reviews and the corresponding review image URLs, we used Scrapy3, a free and open-source web-crawling framework. It accepts a product name as an input and returns product reviews and associated images. The reviews were collected based on five domains (Books, Edible, Electronics, Fashion, and Miscellaneous) for a more fine-grained gold standard dataset. To eliminate noise (HTML tags and special characters) from the textual portion of the dataset, we had to perform some pre-processing operations on the corpus. The Unicode emojis in the product reviews were converted to emoji short text with the help of a Python module called Emoji4. The Python library Textblob4 was used to correct the spellings of many improperly spelled words.

Data Annotation

We assigned three graduate students who are fluent in English to annotate the reviews with appropriate complaint/non-complaint labels and emotion and sentiment tags. Before the annotation process began, the annotation rules were provided with a few examples. To begin, we define an annotation task to determine whether or not a review contains a complaint. If the review has at least one complaint speech act, we consider the entire review to be a complaint. We use the complaint definition from an earlier linguistic study (Cohen and Olshtain 1993) for complaint annotation: “A complaint presents a state of affairs that breaches the writer’s favorable expectation”. For the emotion annotation, we consider Ekman’s six basic emotions (Ekman et al. 1987) (anger, disgust, fear, happiness, sadness, and surprise). For the sentiment annotation, we use three sentiment classes (negative, neutral, positive).

The majority voting technique was used for selecting the final complaint, emotion, and sentiment labels. Reviews with no common emotion or sentiment label (as determined by the three annotators) were excluded. On the annotated dataset, we computed the Fleiss’ kappa (Fleiss 1971) scores

Table 1: Sample instances from the CESAMARD dataset.

Figure 1: Distribution of emotion labels across CESAMARD dataset.

Figure 2: Distribution of sentiment labels across CESAMARD dataset.

instances where the complaint is articulated through the incorporation of both the modalities (text and image). In the first instance, the image implies bad packaging. On the other hand, the textual modality lacks any obvious indicator of disapproval. So the textual review alone is not a correct indicator of a breach of expectation. In the second instance, the textual modality suggests a neutral review, whereas the image modality implies a positive claim. In both cases, there is a mismatch between the two modalities, which signifies that multiple sources of information could provide supplementary indicators for CI. Contrasting input from various modalities increases the model’s capacity to learn the selective patterns that underpin this complex process.

Significance of Emotion and Sentiment

Figure 3(b) shows two sample instances from the CESAMARD dataset that justify the need to incorporate emotion and sentiment into the complaint identification framework. In the first example, the customer’s mixed emotions could be confusing, but the emotion and sentiment labels clarify the customer’s state of mind. Similarly, in the second example, the emotion and sentiment labels give a better insight into the customer’s negative review. Our dataset’s inclusion of emotion and sentiment information allows the model to employ additional information when reasoning about complaints.

Proposed Methodology

In this section, we define our problem and go over the details of the multi-task multi-modal architecture for identify-
ing complaints. The various components of the architecture are detailed in the sections that follow. The overall framework is shown in Figure 4.

Problem Definition:
We intend to learn three closely related tasks simultaneously, including complaint identification (main task), emotion recognition, and sentiment analysis (auxiliary tasks). Let \( (r_k, e_k, s_k, c_k) \) be a set of \( R \) reviews where \( e_k, s_k \), and \( c_k \) depict the matching emotion, sentiment and complaint labels for \( r_k \)th tweet, respectively. Here, \( r_k \in R \), \( e_k \in E \) (emotion classes), \( s_k \in S \) (sentiment classes) and \( c_k \in C \) (complaint classes). Our multi-task learning model’s objective is to maximize the function \( f \) (Eqn 1) that draws a new instance \( r_k \) to its fitting emotion \( e_k \), sentiment \( s_k \) and complaint \( c_k \) label simultaneously.

\[
\text{argmax}(\prod_{k=0}^{R} P(s_k, e_k, c_k | r_k; \theta))
\]

where \( r_k \) is the input sentence whose complaint label \( (c_k) \), emotion label \( (e_k) \) and sentiment label \( (s_k) \) are to be predicted. \( \theta \) denotes the model’s parameters we aim to optimize.

Multi-modal Complaint Identification (MCI)
The proposed MCI framework consists of five principal components: (i) Multi-modal Feature Extraction (MFE) extracts the features from the two modalities (text and image), (ii) Modality Encoders provide corresponding modality encodings by using the uni-modal features acquired from MFE as input, (iii) Attention Mechanism that includes two significant attention mechanisms namely, inter-segment inter-modal attention and contextual inter-modal attention, (iv) Adversarial Loss which ensures the shared layers and task-specific feature space remain mutually exclusive. (v) Output Layer consists of output medium for the three tasks to obtain a generalized representation throughout all the tasks.

Feature Extraction
The process for extracting features across different modalities is detailed below.

Text Features The textual features (T) were obtained using state-of-the-art Sentence Bidirectional Encoder Representations from Transformers (SBERT) model\(^7\). SBERT architecture is a multi-layer bidirectional transformer encoder (Reimers and Gurevych 2019) which is an adaptation of the pre-trained BERT network shown in (Devlin et al. 2019). We employ stsb-bert-base, a bert-base-uncased model which was optimized for Semantic Textual Similarity. SBERT encodes a single sentence into a vector of length 768.

Image Features The images of each product review are first rescaled and normalized. The pre-processed images are sent as inputs to an ImageNet (Deng et al. 2009) pre-trained ResNet-152 (He et al. 2016) image classification model. The output from the image classification model is then passed through a Global Average Pool layer, thus extracting the image features. Each obtained image feature vector (I), \( I \in \mathbb{R}^d \) where \( d = 2048 \) is then reshaped to \( (1 \times d) \) size.

Modality Encoders
Textual Encoding The features \( T \) and \( I \) derived from each of the modalities associated with a review are then passed through three Bi-directional Long Short-Term Memory (BiLSTMs) (Hochreiter and Schmidhuber 1997). For the textual modality, the final hidden state matrix of a review is obtained as \( H_t \in \mathbb{R}^{n_t \times 2d_t} \). Here, \( n_t \) represents the number of hidden units in each LSTM and \( n_t \) is the text length.

Image Encoding The image features \( I \) obtained are passed through a private BiLSTM layer and the Shared BiLSTM layer2. The image features are sent through the private BiLSTM layer (BiLSTM layerp) to obtain hidden states by sequentially encoding these representations. Both the image and textual feature vectors are passed to the shared BiLSTM layer to obtain hidden states with complementary semantic relations between the two modalities. The final hidden state matrix of the image obtained from the private BiLSTM is \( H_i \in \mathbb{R}^{n_i \times 2d_l} \). \( n_i \) is the dimension of the image representations and \( d_l \) is the number of hidden units in each LSTM. Similarly, the shared BiLSTM layer’s final hidden state ma-

\(^7\)https://github.com/UKPLab/sentence-transformers
trix is $H_{sh} \in \mathbb{R}^{n_sh \times 2d_l}$, where $n_{sh} \in \mathbb{R}^{(n_i+n_t)}$.

**Attention Mechanism**

We employ the attention technique (Bahdanau, Cho, and Bengio 2015) to concentrate on the words that contribute the most to the sentence meaning (Att). In the case of textual modality, following the Shared BiLSTM layer_1, we employ three independent task-specific attention layers ($\text{Att}_{COM}$, $\text{Att}_{EMO}$, $\text{Att}_{SENT}$). After the Shared BiLSTM layer_2 there is one attention layer ($\text{Att}_{sh}$) and another attention layer ($\text{Att}_{img}$) after the task-specific BiLSTM layer ($\text{BiLSTM}_p$) in the image modality module.

**Inter-segment Inter-modal Attention ($A_S$):** Motivated by the work in (Chauhan et al. 2020), the inter-segment inter-modal attention is applied to the outputs obtained from the dense layers of the image and the text modalities, respectively. We need to divide both the modalities of our dataset into some fixed number of segments beforehand, as this can only be applied when both the modalities are divided into the same number of segments. The main objective is to learn the dependency of the feature vectors of a segment of the visual modality with the feature vectors of the same segment from the text modality. For each sentence, the feature vectors i.e., $\in \mathbb{R}^d$ obtained from the two modalities i.e., $\in \mathbb{R}^{2\times d}$ are concatenated and then split into $n$-segments i.e., $\in \mathbb{R}^{2\times n}$.

**Contextual Inter-modal Attention ($A_C$):** Many times, a single review constitutes multiple sentences and can be a mixture of complaint and non-complaint sentences. The complaint information of such a review is dependent on the whole context. This encourages us to apply attention to the contributing adjacent sentences, as well as multi-modal representations of the same could benefit the system. In a multi-modal framework, the interaction between modalities of the same sentence is crucial and so is the correlation between modalities across the contexts. This attention mechanism is called contextual inter-modal attention and is motivated by the work in (Ghosal et al. 2018).

**Attention Fusion** We linearly concatenate the computed $A_S$ and $A_C$ vectors with the following $X_{sh}$, $W_1$ and $U_T$ output vectors and pass the concatenated vector (V) through a fully-connected layer. The following equations can be used to represent the flow of information:

\[
W_1 = \text{Dense}_P(\text{Att}_{IMG}(\text{BiLSTM}_p)) \\
X_{sh} = \text{Dense}_S(\text{Att}_{sh}(\text{SBiLSTM}_2)) \\
U_T = \text{Dense}_S(\text{Dense}_C(\text{Att}_{COM}(\text{SBiLSTM}_1))) \\
A_S = [W_1; U_T] \\
A_C = [W_1; U_T] \\
V = [W_1; U_T; A_S; A_C]
\]

Here, ‘;’ indicates the linear concatenation and ‘,’ indicates the inputs of that layer.

**Adversarial Loss**

The adversarial loss strives to mutually exclude the feature space of shared and task-specific layers. We use a similar methodology to (Liu, Qiu, and Huang 2017), in which a task discriminator (Z) maps the shared feature to its primary task. The adversarial loss is calculated as: $L_{adv} =$
\[
\min(\max(\sum_{p=1}^{P} \sum_{q=1}^{Q} (z^p_q \times \log(Z(E(x^p_q))))) \text{ where, } P \text{ denotes the type of tasks, } z^p_q \text{ signifies the actual label amongst } P, \text{ and } x^p_q \text{ is the } q^{th} \text{ example for task } p. \text{ The gradient reversal layer (GRL) (Ganin and Lempitsky 2015) handles the min-max optimization problem.}
\]

Output Layer
The final predictions for emotion and sentiment tasks are generated by averaging the adversarial outputs \((E_{adv} \text{ and } S_{adv})\) and the shared outputs \((E_s \text{ and } S_s)\). For the complaint predictions, the multi-modal complaint output \((C_m)\) is also considered, i.e., the average of \(C_{adv}, C_s \text{ and } C_m\).

Calculation of Loss: For the complaint, emotion, and sentiment tasks, we compute the categorical-cross entropy (CE) losses. The integrated loss function \((L)\) of our proposed MCI system is realized as follows: 
\[
L = x \times L_{CE}^C + y \times L_{CE}^E + z \times L_{CE}^S.
\]
We aggregate the weighted sum of the losses from the three tasks to compute the overall loss. Here, \(x, y,\) and \(z\) are constants ranging from 0 to 1 that determine the loss weights that represent the per-task loss-share to the overall loss.

Experiments, Results, and Analysis
Baselines
• Single-task systems: We develop a SBERT-based single-task deep learning model for complaint detection with only text (STL\(_T\)). The BiLSTM output passes through the attention, dense and outer layer (task-specific). For the multi-modal single-task (complaint) model (STL\(_{T+I}\)) (Pranesh and Shekhar 2020), to extract the image features Visual Geometry Group Network\(^8\) (VGG19) model has been used and the remaining architecture is similar to STL\(_T\).

• Multi-task systems: We develop MTL\(_T\) and MTL\(_{T+I}\) models for multi-task baselines. The textual embeddings are generated from the pre-trained GloVe\(^9\) (Pennington, Socher, and Manning 2014). The embedding layer’s output is forwarded to the word sequence encoder, which analyzes it to extract contextual knowledge from the sentence. For extracting the image features, VGG19\(^10\) is used. The system is composed of a fully-shared BiLSTM layer (256 units), followed by a shared attention layer. The output of the attention layer is passed into the three task-specific dense layers, which are then forwarded to respective output layers. The BERT-Shared Private Model (BSMFM\(_T\)) (Singh and Saha 2021) is another suitable baseline for multi-task framework.

• BERT Multi-modal Multi-task Learning (BMML): This model is similar to the shared private model BSMFM\(_T\). Additionally, it also comprises two attention mechanisms (\(A_S, A_C\)) for the complaint task. For the extraction of image features, pre-trained ResNet-152 along with the global average pool layer has been used.

Ablation models: To understand the impact of emotion and sentiment prediction individually on complaint classification, we build dual-task variants of our proposed framework (MCI\(_{CE}\), MCI\(_{CS}\)). The architectures are similar to the MCI system in other aspects. Furthermore, ablation studies are performed to analyze the importance of each of the special attention mechanisms used (\(A_S, A_C\)) in the MCI framework (MCI\(_{A_S}, MCI_{A_C}\)).

Experimental Setup
We utilize Python-based libraries Tensorflow\(^{11}\) and Scikit-learn\(^{12}\) (Pedregosa et al. 2011) to implement our proposed framework and all baselines. We report the weighted average F1 score and the accuracy of the models. 70% of the CESAMARD dataset was used as training data, 10% for validation, and the rest 20% was used as testing data on all the experimental models. For a fair comparison of the models, a seed value of 42 was chosen, which allowed the models to encounter the same training and testing data. After each of the BiLSTM layers (256 units), we apply a dropout (Srivastava et al. 2014) of 30% each. The output of the task-specific dense layers (128 units) are fed to the softmax layers (smax) for shared outputs. Dense layers of 100 units each are used before sending the text and image modality encodings through the \(A_S\) and \(A_C\) layers. We also employ a dropout of 30% following the fully connected layer to decrease the risk of overfitting. For the inter-segment inter-modal attention, the number of segments \((k)\) is set to 10. In the dense layers, we employ ReLU activation (Glorot, Bordes, and Bengio 2011). Softmax activation with 2, 6, and 3 neurons are used for the output layers for complaint, emotion, and sentiment classification tasks. Categorical cross-entropy is used as the loss function to train across all the channels. The epoch size is set to 100. Adam (Kingma and Ba 2015) with a learning rate of 0.001 is used as the optimizer. The above values are chosen after thorough hyperparameter tuning using the RandomSearch tuner of the Keras tuner API.

Results and Discussion
Please note that this work aims to improve the performance of CI with the help of the other two secondary tasks (ER and SA). Therefore, we state that the results and analysis with CI serve as the key task in all the task combinations.

Table 2 depicts the classification results from the various experiments. As can be observed, incorporating multi-modal cues in the form of text and images significantly enhances the performance of single modality baselines. This enhancement validates the proposed architecture’s efficient usage of interaction among input modalities. This also emphasizes the significance of including multi-modal features for various opinionated text/review analysis tasks. As seen in Table 2, the proposed approach, which includes all three tasks (CI,
Significance of Adversarial Multi-task Architecture: In terms of all the multi-task baselines (MTL-T, MTL-T+I), BSPMF, BMML) these approaches do not consider the adversarial loss. Whereas the proposed model, MCI, incorporates the adversarial loss, which enhances the performance of the multi-task model. We also illustrate the significance of different attention mechanisms for the proposed MCI framework by conducting ablation studies (MCI\textsubscript{AE}, MCI\textsubscript{CS}). Moreover, we also report the results by replacing the SBERT embedding model with Glove embeddings (Pennington, Socher, and Manning 2014) (MTL-T). The results suggest that each of these factors considerably boosted the performance of the proposed MCI framework. All of the results stated here are statistically significant\textsuperscript{13} (Welch 1947).

Comparison with State-of-the-art Technique (SOTA): We also compare our proposed approach with the existing state-of-the-art technique (Jin and Aletras 2020) for single-task CI as we are unaware of any other multi-modal complaint identification framework. SOTA utilizes an array of neural language models boosted by the use of transformer networks. We re-implement it on the CESAMARD dataset and report the results in Table 2. The proposed model outperforms the SOTA technique.

Error Analysis

We discuss possible reasons for the errors in CI task:

- Skewness of Dataset: The CESAMARD dataset’s skewed class distribution influences the proposed MCI model’s predictions. The complaint class (33%) is underrepresented compared to the non-complaint class, due to which the model is biased towards the non-complaint class. It conforms with the practical scenarios where complaints occur less frequently than non-complaints.

- Ironical Instances: Instances having ironic or comments where the underlying tone is positive or neutral, but the instance is of complaint type, the MCI model inaccurately predicts such instances as complaint. For example, ’Biscuits with oil might be a rare combination of Amazon nowadays’. For the above sentence, the predicted class is non-complaint, but the actual class is complaint. One reason could be the neutral undertone and usage of less explicit words to signify complaint.

- Multifold Sentences: Many of the instances in the CESAMARD dataset are lengthy and heterogeneous, covering diverse emotions in a single review. In such scenarios, learning specific complaint features becomes challenging. For example, ’Although it’s not a Microsoft genuine product, it’s good quality and comfortable to use. Price is really reasonable too when compared to its build quality and features.’ predicted class: complaint. The correct class for the given example is non-complaint, but due to the statement’s composite nature and contrasting context, the MCI model misclassifies it as a complaint.

Conclusion and Future Work

In this work, we propose a dual attention-based multimodal (text and images), adversarial multi-task framework for simultaneous optimization of complaint classification, emotion, and sentiment analysis. We have created a novel dataset, CESAMARD, that contains reviews collected from the website of the retail giant Amazon and annotated with the complaint labels and the associated emotion and sentiment categories. The dual attention mechanism employs both inter-segment and contextual inter-modal attention. Inter-segment inter-modal attention uses the relationship between distinct sentence segments across modalities. At the same time, contextual inter-modal attention learns the contextual information for sentence-level complaint prediction across the modalities. Based on experimental results, we can conclude that multi-modality and multi-tasking boost the performance of complaint identification in comparison to its uni-modal and single-task alternatives.

In future, we aim to extend this work with audio, video accompanied with text-based reviews shared on shopping platforms for complaint identification.
