Abstract
We advocate the use of ontologies for relaxing and restraining queries, so that they retrieve either more or less answers, enabling the exploration of a given dataset. We propose a set of rewriting rules to relax and restrain conjunctive queries (CQs) over datasets mediated by an ontology written in a dialect of DL-Lite with complex role inclusions (CRIs). The addition of CRI enables the representation of knowledge about data involving ordered hierarchies of categories, in the style of multi-dimensional data models. Although CRIs in general destroy the first-order rewritability of CQs, we identify settings in which CQs remain rewritable.

Introduction
In Ontology-based data access (OBDA) an ontology provides a conceptual view of a collection of data sources, and can describe knowledge about the domain of interest at a high level of abstraction, using a familiar vocabulary (Poggi et al. 2008). An advantage of having an ontology is that the knowledge can be leveraged to retrieve more complete answers from incomplete data. For example, we consider the following dataset about cultural events and their locations

\[ A_e = \{ \text{Concert}(e_1), \text{CulturEvt}(e_1), \text{Exhibition}(e_1), \text{Venue}(\text{StOpera}), \text{Venue}(\text{VkTheater}), \text{City}(\text{Vienna}), \text{Country}(\text{Austria}), \text{occln}(e_1, \text{StOpera}), \text{occln}(e_1, \text{Vienna}), \text{occln}(e_1, \text{Austria}), \text{locIn}(\text{StOpera}, \text{Vienna}), \text{locIn}(\text{VkTheater}, \text{Vienna}), \text{locIn}(\text{Vienna, Austria}) \} \]

and the following ontology that, among other knowledge, says that concerts and exhibitions are cultural events

\[ \mathcal{T}_e = \{ \text{Concert} \sqsubseteq \text{CulturEvt}, \text{Country} \sqsubseteq \text{Location}, \text{Exhibition} \sqsubseteq \text{CulturEvt}, \text{City} \sqsubseteq \text{Location}, \text{CulturEvt} \sqcap \text{Event}, \text{Venue} \sqsubseteq \text{Location}, \exists \text{occln} \sqsubseteq \text{Event}, \exists \text{occln} \sqsubseteq \text{Location} \}. \]

Using this knowledge, all cultural events (e_1, e_1, and c_1) can be retrieved with a simple conjunctive query (CQ):

\[ q(x) \leftarrow \text{CulturEvt}(x). \]

In OBDA, ontologies are often written in the Description Logics (DLs) of the DL-Lite family (Calvanese et al. 2007). These DLs are tailored towards FO-rewritability of CQs. This means that evaluating a query \( q \) over a dataset \( A \) mediated by an ontology \( \mathcal{T} \) can be reduced to evaluating a query \( q_{\mathcal{T}} \), incorporating knowledge from \( \mathcal{T} \) over \( A \) alone, which amounts to standard query evaluation in relational databases. In our example, a rewriting of \( q \) is the following query:

\[ q_{\mathcal{T}}(x) \leftarrow \text{CulturEvt}(x) \lor \text{Exhibition}(x) \lor \text{Concert}(x). \]

In this paper, we advocate a novel use of ontologies complementary to OBDA query answering. Namely, we use ontologies to modify queries, relaxing or restraining them, so that they can retrieve either more or less answers over a given dataset. This can help users reflect their information needs and flexibly explore datasets. We build on the observation that query restrictions can be obtained using the standard DL-Lite rewriting rules (Calvanese et al. 2007). For example, \( q_e(x) \leftarrow \text{Concert}(x) \) is a restriction of \( q \), and it occurs as a disjunct in its rewriting \( q_{\mathcal{T}} \). Moreover, these rewriting rules have natural ‘counterparts’ that produce relaxations.

In our running example, if answers to a query for \( \text{concerts} \) are too scarce, one might get more answers by relaxing it to one asking for all cultural events. Conversely, if a query for cultural events produces too many answers, it is possible to restrict it to events of a specific type, for instance concerts.

Notably, there are intuitive answers and reformulations that cannot be produced with the standard DL-Lite rewriting rules and their counterparts. For example, consider a query retrieving concerts occurring in Vienna:

\[ q_2(x) \leftarrow \text{Concert}(x), \text{occln}(x, y), y = \text{Vienna}. \]

In the presence of standard DL-Lite ontologies, there are no answers to \( q_2 \) when evaluated over \( (\mathcal{T}_e, A_e) \), although \( c_1 \) may be considered an answer to \( q_2 \) according to the intuition that if an event occurs in a venue located in a city, then it occurs in that city. In order to capture this kind of knowledge, we propose to extend the expressive power of DL-Lite with complex role inclusions (CRIs).

For instance, adding

\[ \text{occln} \cdot \text{locIn} \sqsubseteq \text{occln} \]

(1)

to our example captures the intuition above, and makes \( c_1 \) an answer of \( q_2 \). The addition of CRIs enables DL-Lite to leverage hierarchical knowledge not captured by subclass relations. Indeed, venues, cities, and countries can be seen as different levels of a dimension we can call Location. Similarly, a Time dimension could include days, months, and...
years, while the physical parts of complex objects may be hierarchically ordered along a Component dimension. Dimensions lie at the core of the so-called multi-dimensional data model (Hurtado and Mendelzon 2002) used for storing and accessing data at different granularity levels. We show that the addition of CRIs enables DL-Lite to leverage dimensional knowledge. Unfortunately, CRIs in DLs are computationally costly: unrestricted they easily lead to undecidability (Horrocks and Sattler 2004), and critically for DL-Lite, even one fixed CRI destroys FO-rewritability of CQs. For this reason we devote a section to defining an expressive setting that supports CRIs and enjoys FO-rewritability.

Along with the addition of CRIs, we propose a set of reformulation rules operating not only along the subclass and subrole relations, but also along CRIs. For example we can use (1) to reformulate the query

$q_3(x) \leftarrow \text{Concert}(x), \text{occIn}(x, y), \text{City}(y)$,

from all concerts occurring in a city, to those occurring in some more specific location:

$q'_3(x) \leftarrow \text{Concert}(x), \text{occIn}(x, z), \text{locIn}(z, y), \text{City}(y)$.

We propose another set of rules that not only use the knowledge from the ontology, but also use instances of concepts and relations, as well as inclusions between concepts guaranteed to hold in the current dataset. For example, we can restrict $q_2$ to ask for concerts in the State Opera, or relax it to concerts in Austria. Such reformulations are similar to the drilling down and rolling up operations used for navigating along a dimension. Note that these reformulations are not data independent, but instead rely on the current dataset $A_c$.

Preliminaries

As usual, $N_{C}$, $N_{R}$, and $N_{I}$ are countable infinite alphabets of concept, role, and individual names, respectively. In what follows, we will use $A, A'$ to denote elements in $N_{C}$, $s, p, p'$, elements in $N_{R}$, and $a, b$, elements in $N_{I}$. In DL-Lite$^H$ (Artale et al. 2009), concepts $B$ are built according to the grammar

$$B ::= A \mid \exists r\cdot B \mid \top \mid \bot,$$

where $p^-$ is called an inverse role. The set of roles is defined as $N_{R}^\pm = N_{R} \cup \{p^- | p \in N_{R}\}$.

We assume w.l.o.g. that a DL-Lite$^H$ TBox (or ontology) $\mathcal{T}$ is a finite set of concept inclusion axioms taking the following normal form $A \sqsubseteq A', A \sqsubseteq \exists p\cdot A, \exists p \sqsubseteq A, p \sqsubseteq s, \top \sqsubseteq s$, together with a set of disjointness axioms of the form $\neg \exists p\cdot A, \neg \exists p'\cdot A'$. An ABox (or dataset) $\mathcal{A}$ is a finite set of assertions $A(a)$, and $p(a, b)$. We denote the set of individuals occurring in $\mathcal{A}$ as $\text{ind}(\mathcal{A})$. A knowledge base (KB) is a pair $K = (\mathcal{T}, \mathcal{A})$. The semantics is defined in terms of interpretations $I = (\Delta^I, \cdot^I)$ consisting of a non-empty domain $\Delta^I$ and an interpretation function $\cdot^I$, that complies with the standard name assumption i.e., $a^I = a$ for every individual. Satisfaction is defined as usual. For $K = (\mathcal{T}, \mathcal{A})$ we write $I \models K$ if $I$ satisfies every axiom in $\mathcal{T}$ and every assertion in $\mathcal{A}$, and in that case we say that $I$ is a model of $K$. We say $K$ is satisfiable if it has a model.

We consider the class of conjunctive queries and unions thereof. A term is either an individual name or a variable. A conjunctive query (CQ) is a first order formula with free variables $\vec{x}$ and existential variables $\vec{y}$ that takes the form $q(\vec{x}) \leftarrow \varphi(\vec{x}, \vec{y})$, with $\varphi$ a conjunction of atoms of the form $A(x), r(x, y), \text{and } t = t'$, where $t, t'$ range over terms. Instance queries are CQs with exactly one atom and no existential variables. The terms occurring in $q$ are denoted terms($q$), and the variables vars($q$). The free variables $\vec{x}$ of a query are called query variables.

Let $I$ be an interpretation, $q(\vec{x})$ a CQ. An answer to $q$ in $I$ is a tuple $\vec{a}$ of elements from $\Delta^I_{\vec{x}}$ that satisfy $\varphi(\vec{a}, \vec{b})$, with $\vec{b}$ for each individual $b$, (ii) $\vec{b} = b$ for each individual $b$, (iii) $I \models P(\varphi(\vec{a}))$ for each atom $P(\vec{a})$ in $q$, and (iv) $\pi(t) = \pi(t')$ for each atom $t = t'$ in $q$, and in that case we write $I \models q(\vec{a})$. The map $\pi$ is called a match for $q$ in $I$. The certain answers of $q(\vec{x})$ over $\mathcal{T}$ are denoted cert($q$, $\mathcal{T}$, $\mathcal{A}$) and defined as set of all the tuples $\vec{a}$ such that $\mathcal{I} \models q(\vec{a})$ for every model of $\mathcal{T}$.

When we talk about the computational complexity of query answering, we mean the following decision problem: given a KB $K$, a query $q$, and a tuple of individuals $\vec{a}$, check whether $\vec{a} \in \text{cert}(q, \mathcal{T}, \mathcal{A})$.

DL-Lite with Complex Role Inclusions

In this section, we study an extension of DL-Lite$^H$ with complex role inclusions, which are critically important in our approach to ontology-based relaxing and restraining of queries. A complex role inclusion (CRI) is an expression of the form $\langle r \cdot s \sqsubseteq t \rangle$, with $r, s, t \in N_{R}^\pm$. An interpretation $\mathcal{I} = (\Delta^I, \cdot^I)$ satisfies $\langle r \cdot s \sqsubseteq t \rangle$ if $\langle d_1, d_2 \rangle \in r^I$, $\langle d_2, d_3 \rangle \in s^I$, imply $\langle d_1, d_3 \rangle \in t^I$, for all $d_1, d_2, d_3 \in \Delta^I$.

The addition of CRIs to DLs may lead to undecidability of reasoning (Horrocks and Sattler 2004), hence syntactic conditions such as regularity (Kazakov 2010) are often needed.

In what follows, we assume a set $N_{R}^\pm \subseteq N_{R}^\pm$ of simple roles closed w.r.t. inverses (i.e. $s \in N_{R}^\pm$ implies $s^- \in N_{R}^\pm$); each $r \in N_{R}^\pm \setminus N_{R}$ is a non-simple role. We extend DL-Lite$^H$ with CRIs as follows:

Definition 1 (DL-Lite$^H_{CR}$). A DL-Lite$^H_{CR}$ TBox $\mathcal{T}$ is a DL-Lite$^H$ TBox that may also contain CRIs, and satisfies

- $s \in N_{R}^\pm$ and $t \in N_{R}^\pm \setminus N_{R}$, for every $r \cdot s \sqsubseteq t$;
- if $s \sqsubseteq t$ is in $\mathcal{T}$ and $t \in N_{R}^\pm$, then $s \in N_{R}^\pm$.

Properties such as FO-rewritability are affected by CRIs. Indeed, using a single CRI $r \cdot s \sqsubseteq r$, it is possible to express that $r$ corresponds to the transitive closure of role $s$ on a given graph. Since KB satisfiability in DL-Lite with transitive roles is NLOGSPACE-hard, the following follows easily.

Lemma 1. (Artale et al. 2009) Answering instance queries in DL-Lite$^H_{CR}$ is NLOGSPACE-hard in data complexity, already for TBoxes consisting of the CRI $r \cdot s \sqsubseteq r$ only.

Therefore CQs are not FO-rewritable w.r.t. DL-Lite$^H_{CR}$ TBoxes. Our goal next is to present a restricted DL-Lite$^H_{CR}$-based setting that is expressive enough to capture the desired scenarios and that still supports FO-rewritability. To this end, we first define a fragment of DL-Lite$^H_{CR}$ that disallows cyclic dependencies among roles in CRIs. This non-recursive fragment of DL-Lite$^H_{CR}$ is quite expressive.
(e.g., KB satisfiability is not tractable) and supports FO-rewritability of CQs, yet it is not sufficient to cover our motivating example that involves recursion. To overcome this, we carefully relax the non-recursiveness requirement so that desired cyclic dependencies in CRIs are allowed, obtaining recursion-safe DL-Lite$^HR_{non-rec}$. We then identify a sufficient condition (over ABoxes) for eliminating recursive CRIs, return to the non-recursive setting, and regain FO-rewritability. Moreover, we show that satisfiability of such knowledge bases is tractable.

**Non-recursive DL-Lite$^HR_{non-rec}$**

We start by defining a suitable notion of recursive CRIs. For a DL-Lite$^HR_{non-rec}$ TBox $T$, the recursion graph $\mathcal{G}_T$ of $T$ is the directed graph that contains (i) a node $v_A$ for each concept name $A$ in $T$, (ii) a node $v_r$ for each role name $r$ in $T$, and (iii) there exists an edge from a node $v_{P'}$ to a node $v_P$ whenever $P$ occurs on the left-hand-side and $P'$ on the right-hand-side of an axiom in $T$. A CRI $t \leadsto r \subseteq s$ is recursive w.r.t. a TBox $T$ if $\mathcal{G}_T$ has a path from $v_t$ or $v_s$ to $v_r$. In this case we also say that $r$ is a recursive role in $T$.

**Definition 2.** A DL-Lite$^HR_{non-rec}$ TBox is a DL-Lite$^HR$ TBox $T$ without recursive CRIs.

We now define query rewriting rules for non-recursive DL-Lite$^HR_{non-rec}$. For a CQ $q$, we denote by $z^q$ an arbitrary variable not occurring in $q$; we will use $z^q$ in the query rewriting rules through the rest of the paper. An atomic substitution $\theta = [\Gamma_1/\Gamma_2]$ can be applied to $q$ if $\Gamma_1 \subseteq q$ and the effect is to replace atoms $\Gamma_1$ with atoms $\Gamma_2$ in $q$.

**Definition 3.** Let $T$ be a DL-Lite$^HR_{non-rec}$ TBox. For CQs $q, q'$, we write $q \rightarrow^\star q'$ whenever $q'$ is obtained by

- **B1** replacing $x$ by $y$ in $q$, for $x, y \in \text{vars}(q)$
- or by applying an atomic substitution $\theta$ to $q$, as follows:
  - **S1** $\theta = [A_1(x)/A_1(x)]$, if $A_1 \not\subseteq A_2 \wedge A_2(x) \in q$;
  - **S2** $\theta = [r(x,y)/A(x)]$, if $A \not\subseteq \exists r \subseteq T \wedge r(x, y) \in q$ and $y$ is a non-answer variable occurring only once in $q$;
  - **S3** $\theta = [A_1(x)/r(x, z^q)]$, if $\exists r \not\subseteq A \subseteq T \wedge A(x) \in q$;
  - **S4** $\theta = [s(x,y)/r(x,y)]$, if $\exists s \not\subseteq T \wedge s(x, y) \in q$;
  - **S5** $\theta = [s(x,y)/r(y, x)]$, if $\exists s \not\subseteq T \wedge s(x, y) \in q$;
  - **S6** $\theta = [r(x,y)/\{t(x,z^q), s(z^q, y)]\}$, if $t \cdot s \not\subseteq r \subseteq T\wedge r(x,y) \in q$.

By $q \rightarrow^\star q'$ we denote the reflexive, transitive closure of $q \rightarrow^\star q'$. The rewriting of $q$ w.r.t. $T$ is the set $\text{rew}(q,T)$ of all queries (modulo isomorphisms) $q'$ such that $q \rightarrow^\star q'$. Moreover, the absence of recursive CRIs in $T$ ensures that $\text{rew}(q,T)$ is finite and can be effectively computed.

**Lemma 2.** For a DL-Lite$^HR_{non-rec}$ TBox $T$ and CQ $q$, the size of each $q' \in \text{rew}(q,T)$ is bounded by a polynomial, and can be computed in polynomial time, in the size of $T$ and $q$.

We can now show FO-rewritability of CQs in DL-Lite$^HR_{non-rec}$.

**Theorem 1.** Let $T$ be a DL-Lite$^HR_{non-rec}$ TBox, $q$ a CQ. For every ABox $A$ such that $(T, A)$ is satisfiable, we have:

$$\text{cert}(q, T, A) = \bigcup_{q' \in \text{rew}(q, T)} \text{cert}(q', \emptyset, A).$$

Surprisingly, unlike the extension with transitive roles, KB satisfiability for non-recursive CRIs is intractable.

**Theorem 2.** (i) Satisfiability of DL-Lite$^HR_{non-rec}$ KBs is coNP-complete for combined complexity, and (ii) CQ answering over consistent DL-Lite$^HR_{non-rec}$ KBs is in AC$^0$ for data, and NP-complete for combined complexity.

For (ii), the upper bound is obtained similarly as for standard DL-Lite: KB satisfiability can be reduced to UCQ answering, using a CQ $q_\alpha$ for testing whether each disjointness axiom $\alpha$ is violated. By Lemma 2 and Theorem 1, an NP procedure can guess one such $q_\alpha$, guess a $q'_\alpha$ in its rewriting, and evaluate $q'_\alpha$ over $A$. The lower bound can be shown by a reduction of the complement of 3SAT to KB satisfiability.

For (ii), data complexity follows from Theorem 1, while for combined complexity, NP-hardness is inherited from CQ evaluation in relational databases. An NP procedure for answering $q$ over $A$ w.r.t. $T$ can guess some $q' \in \text{rew}(q,T)$ (which is polynomial in $q$ and $T$) and a map $\pi : \text{vars}(q') \rightarrow \text{vars}(A)$, and then verify whether $\pi$ is a match of $q'$ in $A$, which can be done in polynomial time.

**Recursion-safe DL-Lite$^HR_{non-rec}$**

In DL-Lite$^HR_{non-rec}$ we cannot express CRIs like the one in our motivating example. To overcome this, we introduce an FO-rewritable fragment of DL-Lite$^HR$ able to express certain kind of recursive CRIs.

**Definition 4 (DL-Lite$^HR_{rec-safe}$).** A recursion safe DL-Lite$^HR$ TBox is a TBox $T$ where every CRI $r_1 \cdot s \subseteq r_2 \subseteq T$ satisfies the following conditions.

- If $r_2$ is a recursive role, then every cycle in $\mathcal{G}_T$ containing $r_2$ has length at most one, and $r_1 = r_2$.
- There is no axiom of the form $B \sqsubseteq \exists r \subseteq T \wedge t \sqsubseteq \exists s \subseteq T \wedge s \sqsubseteq t$, where $\exists r$ denotes the reflexive and transitive closure of $s \sqsubseteq t \subseteq s \sqsubseteq T$.

The first condition restricts recursion to a simple form; we show later that this form of recursion can be eliminated when the ABox satisfies certain conditions. The second, on the other hand ensures that every CRI is ‘guarded’ by a simple role that is not existentially implied. Thus, for query answering, we can assume that only ABox individuals are connected by these guarding simple roles, and thus edges in the extension of recursive roles ‘produced’ by CRIs will always contain at least one individual. Note, for example, that $T_\infty$ extended with (1) is recursion safe, since the simple role $\text{locIn}$ in the CRI is not existentially implied by other axioms in $T_\infty$. In contrast to non-recursive DL-Lite$^HR$, in combined complexity KB satisfiability and instance query answering are tractable for DL-Lite$^HR_{rec-safe}$ KBs.

**Theorem 3.** KB satisfiability and answering instance queries in DL-Lite$^HR_{rec-safe}$ are in PTIME for combined complexity.

The proof of the theorem above relies on the construction of a particular canonical model. Let $K = (T, A)$ be a DL-Lite$^HR_{rec-safe}$ KB. We define an interpretation $\mathcal{E}_{T,A}$ with
domain $\Delta^{E,T,A} = D_0 \cup D_1 \cup D_2$, where 

$$D_0 = \text{ind}(A), \quad D_1 = \{c_{ar} \mid a \in D_0, B \subseteq r \in T\},$$

$$D_2 = \{c_v \mid B \subseteq r \in T\},$$

and such that each concept, respectively each role name in $K$ is interpreted as the minimal subset of $\Delta^{E,T,A}$, respectively of $\Delta^{E,T,A} \times \Delta^{E,T,A}$, such that for all concepts $A$, $B$ and all roles $r, r_1, r_2, s, t$ in $K$, the following conditions hold:

- If $A(d) \in A$ then $d \in A^{E,T,A}$, and if $r(d, d') \in A$ then $(d, d') \in r^{E,T,A}$.
- If $B \subseteq r \in T$, then $(d, c_{ar}) \in r^{E,T,A}$ if $d \in B^{E,T,A} \cap D_0$, and $(d, c_v) \in r^{E,T,A}$ if $d \in B^{E,T,A} \cap (D_1 \cup D_2)$.
- If $B \subseteq A \in T$ and $d \in B^{E,T,A}$ then $d \notin A^{E,T,A}$.
- If $r_1 \subseteq r_2 \in T$ and $(d, d') \in r_1^{E,T,A}$ then $(d, d') \in r_2^{E,T,A}$.
- If $r_1 \subseteq r_2 \in T$ and $(d, d') \in r_1^{E,T,A}$ then $(d', d) \in r_2^{E,T,A}$.
- If $r \in T$ and $(d, d') \in r^{E,T,A}$ and $(d', d'') \in s^{E,T,A}$ then $(d, d'') \in t^{E,T,A}$.

It can be readily verified that $\Delta^{E,T,A}$ is of polynomial size in $K$, and that whenever $K$ is satisfiable then $\Delta^{E,T,A} \models K$. Moreover, canonicity of $\Delta^{E,T,A}$ is given by the following.

**Claim 1.** For any (satisfiable) DL-Lite$_{\text{rec-safe}}$ KB $(T, A)$ and any instance query $q$,

$$\text{cert}(q, T, A) = \text{ans}(q, \Delta^{E,T,A}).$$

Recall that by Lemma 1 DL-Lite$_{\text{rec-safe}}$ TBoxes are not FO-rewritable in general. However, we will show that recursive CRIs can be eliminated provided that they are only relevant on paths of bounded length in models of $K$. We formalize this intuition next.

**Definition 5 (k-bounded ABox).** Let $T$ be a DL-Lite$_{\text{HR}}$ TBox. For $S$ a set of simple roles, an $S$-path of length $n$ between $a$ and $b$ in $\text{ind}(A)$ w.r.t. $T$ is a sequence of different pairs of individuals $(d_0, d_1), (d_1, d_2), \ldots, (d_{n-1}, d_n)$ such that $d_0 = a$, $d_n = b$ and for each $(d_i, d_{i+1})$, $0 \leq i < n$, there exists $s' \subseteq T$ such that $s' \subseteq T$ for some $s \in S$.

Given an ABox $A$ and some $k \geq 0$, we say that $A$ is $k$-bounded for $T$ if for each $S_T = \{ s \mid r \in S \subseteq T \}$ there is no $S_T$-path of length larger than $k$ in $A$.

If the given ABox is $k$-bounded for the given $k$, recursive CRIs can be unfolded into non-recursive ones. Therefore, queries can be rewritten using a TBox in which all recursive CRIs have been unfolded.

**Definition 6 (k-unfolding, k-rewriting).** For an arbitrary DL-Lite$_{\text{HR}}$ TBox $T$, and fixed $k \geq 0$, a $k$-unfolding of $T$ is a DL-Lite$_{\text{HR}}$ TBox $T_k$ obtained by replacing each $r \in T$ with the axioms

$$\forall r_{j-1} \cdot s \subseteq r_j \quad r \subseteq r_0 \quad r_j \in T \quad (1 \leq j \leq k),$$

where $r$ and $r_j$ are fresh role names. For a CQ $q$, let $\hat{q}$ be the query obtained from $q$ by replacing for every $r \cdot s \subseteq r \in T$, each $r(x, y) \in q$ by $\hat{r}(x, y)$.

For $k$-bounded ABoxes, rew($\hat{q}$, $T_k$) is an FO-rewriting of $q$.

**Theorem 4.** Let $T$ be a DL-Lite$_{\text{HR}}$ TBox $T_k$ a $k$-unfolding of $T$, for some $k \geq 0$, and $q$ a CQ over the signature of $T$. Then, for every $k$-bounded ABox $A$:

$$\text{cert}(q, T, A) = \bigcup_{\hat{q} \in \text{rew}(q, T_k)} \text{cert}(\hat{q}, \emptyset, A).$$

**Query Reformulations**

In this section we propose two sets of rules for relaxing and restraining queries. The first one uses axioms in the ontology to guide the reformulation. Essentially, these are based on the usual rules for query rewriting and on suitable counterparts, resulting in restrictions and relaxations, respectively. The second set of rules are analogous but use dependencies that hold for a given dataset instead of axioms in the ontology. The goal of these rules is to provide a simple approach for reformulating queries, which is intuitive, computationally inexpensive, and that can leverage multidimensional knowledge.

**Ontology-based Reformulations**

The query rewriting rules B1 and S1–S6 for DL-Lite$_{\text{Ont-rec}}$ produce restrainings of a given query in the sense that the answers of the resulting query are necessarily contained in the answers of the original one.

**Definition 7.** Let $T$ be a DL-Lite$_{\text{HR}}$ TBox. Given a pair of CQs $q$, $q'$, we write $q \rightarrow_T q'$ if $q \rightarrow_T q'$, and call $q'$ a restraining of $q$ w.r.t. $T$.

These reformulations are ontology-based because they depend on the axioms of $T$ only, and they are restrainings for every dataset mediated by $T$.

**Proposition 1.** Let $T$ be a DL-Lite$_{\text{HR}}$ TBox. For any two CQs such that $q_1 \rightarrow_T q_2$ and every ABox $A$, we have that $\text{cert}(q_2, T, A) \subseteq \text{cert}(q_1, T, A)$.

**Example 1.** Let $T_0$ be as above. For the following queries

$$q(x) \leftarrow \text{CultEvT}(x), \text{occIn}(x, y), \text{City}(y)$$

$$q_1(x) \leftarrow \text{Concert}(x), \text{occIn}(x, y), \text{City}(y)$$

$$q_2(x) \leftarrow \text{Concert}(x), \text{occIn}(x, z), \text{loCin}(z, y), \text{City}(y)$$

it holds that $q \rightarrow_T q_1 \rightarrow_T q_2$ since by applying B1 using Concert $\subseteq$ CultEvT $\in T_0$ we obtain $q_1$, and further by applying S6 using (1) we obtain $q_2$.

We have seen that the query rewriting rules that ‘apply’ the axioms in a right-to-left fashion provide natural means to restrain queries. The natural next step is to define analogous rules that use the axioms in a left-to-right fashion to relax queries. Note that in the next definition, rules G1–G6 are, essentially, the duals of rules S1–S6, while rule R1 simply allows us to relax a query by dropping an atom.

**Definition 8.** Let $T$ be a DL-Lite$_{\text{HR}}$ TBox. For CQs $q$, $q'$, we write $q \rightarrow_T q' \quad$ whenever $q'$ is obtained from $q$ by

- R1 removing an atom $x = a$ or an atom $A(x)$ with $x$ a non-answer variable,

or by applying an atom substitution $\theta$ as follows:

- G1 $\theta = [A_1(x)/A_2(x)],$ if $A_1 \subseteq A_2 \in T$ and $A_1(x) \in q$;

- G2 $\theta = [A(x)/r(x, z^2)],$ if $A \subseteq r \in T$ and $A(x) \in q$;

- G3 $\theta = [r(x, y)/A(x)],$ if $\exists r \subseteq A \in T, r(x, y) \in q$ and $y$ is a non-answer variable occurring only once in $q$;

- G4 $\theta = [r(x, y)/s(x, y)],$ if $r \subseteq s \in T$ and $r(x, y) \in q$;

- G5 $\theta = [r(x, y)/s(x, y)],$ if $r \subseteq s \in T$ and $r(x, y) \in q$;
Example 2. Let $T_e$ be as above, and take the queries

\[ q(x) \leftarrow \text{Concert}(x), \text{occIn}(x,y), \text{locIn}(y,z), z = \text{Vienna}, \]
\[ q_1(x) \leftarrow \text{CulturEv}(x), \text{occIn}(x,y), y \in A, z = \text{Vienna}; \]
\[ q_2(x) \leftarrow \text{CulturEv}(x), \text{occIn}(x,z), z = \text{Vienna}. \]

it holds that $q \leadsto q_1 \leadsto q_2$, since by applying G1 using \text{Concert} $\sqsubseteq \text{CulturEv}$ $\in T_e$ we obtain $q_1$ and further by applying G6 using (1) we get $q_2$. \(\triangle\)

The following result is the analogous of Proposition 1.

**Proposition 2.** Let $T$ be a DL-Lite$_{\HR}$ TBox. For any two CQs, such that $q_1 \rightarrow q_2$, and every ABox $A$, we have that $\text{cert}(q_1, T, A) \subseteq \text{cert}(q_2, T, A)$.

### Data-dependent Query Reformulations

The query reformulation rules above might miss interesting reformulations. For instance, in our running example, a query relaxation from concerts in Vienna, to concerts at some location in Austria, or a restraining to concerts at the State Opera would be meaningful. For this reason, we define data-dependent query reformulations that assume a fixed dataset, and use assertions and dependencies that hold for it as if they were axioms in the ontology. In our running example, since a quick inspection at $A_e$ tells us that every existing venue is located in a city, we could use this to relax the query

\[ q(x) \leftarrow \text{Event}(x), \text{occIn}(x,y), \text{Venue}(y) \]
\[ q'(x) \leftarrow \text{Event}(x), \text{occIn}(x,y), \text{locIn}(y,z), \text{City}(z). \]

We note that such a reformulation could be done using rule S2, if we had an inclusion $\text{Venue} \subseteq \exists \text{locIn.City}$ in the TBox. But if we do not have such an axiom and it is not possible or desirable to add it, the rules below rely on

$\text{cert}(\text{Venue}(x), T_e, A_e) \subseteq \text{cert}(\exists \text{locIn.City}(x), T_e, A_e)$

to enable such a reformulation.

We define first data-dependent restraining rules of two kinds. First we have rules that use entailed assertions. For example, if $K \models A(x)$ and $q$ contains an atom $A(x)$, then we can restrain $q$ by equating $x$ and $a$, as done by rule (SA1). Similarly with role assertions: if $K \models r(a,b)$ and $r(x,y)$ is in $q$, with (SA2) we can equate $x$ to $a$, or $y$ to $b$. We can also use $K \models r(a,b)$ to replace $r(x,y)$, $y = b$ by $x = a$ if $y$ is a non-answer variable that does not occur elsewhere in $q$; see (SA3).

The second kind of rules (SD1–SD5) use dependencies of the form $\text{cert}(q_1, T, A) \subseteq \text{cert}(q_2, T, A)$, written $q_1 \subseteq (T, A) q_2$ for short. They are similar to the rules in the previous section, but we may now replace $B(x)$ by $A(x)$ not only when $A \subseteq B$ is in $T$, but also when the weaker condition $A(x) \subseteq K B(x)$ holds. Such replacements are also possible for some more complex pairs of atoms. For example, if $\exists r. B(x) \subseteq K A(x)$, then $A(x)$ can be replaced by $r(x,y), B(y)$ to restrain $q$. This would be similar to having in Definition 3 a rule for (non-DL-Lite) axioms $\exists r. B \subseteq A$.

The relaxation rules are dual to the restraining ones. For example, (GA1) is dual to (SA1): if the query is equating some variable $x$ to $a$ and $a$ is an instance of $A$, then we can replace $x = a$ by $A(x)$, thus allowing $x$ to be any instance of $A$, rather than just $a$. Note that there is no dual to (SA2) since it would simply need to drop $x = a$ or $y = b$ from $q$, but this does not depend on the data and is captured by (R1).

**Definition 9.** Let $K = (T, A)$ be a DL-Lite$_{HR}$ KB.

For CQs $q, q'$, we write $q \rightarrow q'_K$ if $q \rightarrow q'_T$ or $q'$ is obtained from $q$ using atom substitution $\theta$ as follows:

SA1 $\theta = [x = a], A(x) \subseteq K A(a)$;

SA2 $\theta = [0/x = a] \text{ or } \theta = [0/y = b], r(x,y) \subseteq K r(a,b)$;

SA3 $\theta = [(r(x,y), y = b)/x = a], r(x,y), y = b \in q, y \text{ does not occur elsewhere in } q$ and $K \models r(a,b)$;

SD1 $\theta = [A_2(x)/A_1(x)], A_1(x) \subseteq K A_2(x)$ and $A_2(x) \in q$;

SD2 $\theta = [(r(x,y), A'(y))/A(x)], A'(x) \subseteq K \exists r.A'(x)$, and $r(x,y), A'(y) \in q$ such that $y$ does not occur elsewhere in $q$;

SD3 $\theta = [A(x)/\{r(x,y), A'(y)/r(x,y)\}], A(x) \subseteq K A(x)$ and $A(x) \in q$;

SD4 $\theta = [s(x,y)/r(x,y)], r(x,y) \subseteq K s(x,y)$ and $s(x,y) \in q$;

SD5 $\theta = [(r(x,y), A'(y))/\{p(x,y), A'(y)\}], r(x,y), A'(y) \in q, y \text{ does not occur elsewhere in } q$ and $\exists p.A'(x) \subseteq K \exists r.A'(x)$.

Further, we write $q \rightarrow q'_T$ if $q \rightarrow q'_K$ or $q'$ is obtained from $q$ using atom substitution $\theta$ as follows:

GA1 $\theta = [x = a/A(x)], x = a \in q$ and $K \models A(a)$;

GA3 $\theta = [x = a/r(x,y), y = b], x = a \in q$ and $K \models r(a,b)$;

GD1 $\theta = [A_1(x)/A_2(x)], A_1(x) \subseteq K A_2(x)$ and $A_2(x) \in q$;

GD2 $\theta = [A(x)/\{r(x,y), A'(y)/r(x,y)\}], A(x) \subseteq K \exists r.A'(x)$ and $A(x) \in q$;

GD3 $\theta = [(r(x,y), A'(y))/A(x)], A'(x) \subseteq K A(x)$ and $r(x,y), A'(y) \in q$ such that $y$ does not occur elsewhere in $q$;

GD4 $\theta = [r(x,y)/s(x,y)], r(x,y) \subseteq K s(x,y)$ and $r(x,y) \in q$;

GD5 $\theta = [p(x,y), A'(y)/\{r(x,y), A(y)\}], p(x,y), A'(y) \in q, y \text{ does not occur elsewhere in } q$ and $\exists p.A'(x) \subseteq K \exists r.A(x)$.

**Example 3.** Let $K_e = (T_e, A_e)$ be as above. For CQs

\[ q(x) \leftarrow \text{Concert}(x), \text{occIn}(x,y), y = \text{Vienna}, \]
\[ q_1(x) \leftarrow \text{Concert}(x), \text{occIn}(x,y), \text{locIn}(y,z), z = \text{Austria}, \]
\[ q_2(x) \leftarrow \text{Concert}(x), \text{occIn}(x,y), \text{locIn}(y,z), \text{Country}(z), \]
\[ q_3(x) \leftarrow \text{Concert}(x), \text{occIn}(x,y), \text{City}(y), \]

we have that $q \rightarrow q'_K q_1 \rightarrow q'_K q_2$ since $q_1$ is obtained by applying GA3 to $q$ using $K_e \models \text{locIn(Vienna, Austria)}$ and $\exists r. B(x) \subseteq K A(x)$, then $A(x)$ can be replaced by $r(x,y), B(y)$ to restrain $q$. This would be similar to having in Definition 3 a rule for (non-DL-Lite) axioms $\exists r. B \subseteq A$. The relaxation rules are dual to the restraining ones. For example, (GA1) is dual to (SA1): if the query is equating some variable $x$ to $a$ and $a$ is an instance of $A$, then we can replace $x = a$ by $A(x)$, thus allowing $x$ to be any instance of $A$, rather than just $a$. Note that there is no dual to (SA2) since it would simply need to drop $x = a$ or $y = b$ from $q$, but this does not depend on the data and is captured by (R1).
is obtained from \( q_1 \) by applying GA1 using \( K_e \models \text{Country}(\text{Austria}) \).

We can now choose to restrain \( q_2 \) and obtain \( q_3 \) by applying SD2 on \( q_2 \) using \( \text{City}(x) \subseteq K_e \exists \text{locIn}. \text{Country}(x) \), hence \( q_2 \models K_e \subseteq q_3 \). Note that \( q_3 \) can also be obtained as a relaxation of \( q \) with GA1 and \( K_e \models \text{City}(\text{Vienna}) \), thus \( q \models q_3 \).

Our data-driven rules indeed relax and restrain queries when evaluated over \((\mathcal{T}, \mathcal{A})\), but not for any arbitrary ABox.

**Proposition 3.** For CQs \( q_1, q_2 \) and DL-Lite\(^{HR} \) KB \((\mathcal{T}, \mathcal{A})\):

- (g) \( q_1 \models K_e \subseteq q_3 \) implies \( \text{cert}(q_1, \mathcal{T}, \mathcal{A}) \subseteq \text{cert}(q_2, \mathcal{T}, \mathcal{A}) \), and
- (s) \( q_1 \models K_e \subseteq q_3 \) implies \( \text{cert}(q_2, \mathcal{T}, \mathcal{A}) \subseteq \text{cert}(q_1, \mathcal{T}, \mathcal{A}) \).

**Modeling Multi-dimensional Data**

In this section we show that recursion safe DL-Lite\(^{HR} \) together with \( k \)-bounded ABoxes, are well-suited to describe this kind of multi-dimensional knowledge in the setting of OBDA. In the multi-dimensional data model (Hurtado and Mendelzon 2002), the data-schema is usually formalized as a set of dimensions, comprising a finite set of categories and a partial order between them, sometimes called child-parent relation. The model also considers a representation at the instance level that defines members for each category, and a child-parent relation between members of connected categories. In Figure 1 a dimension and instance of some Location hierarchy are illustrated, which make use of concepts from \( \mathcal{T}_e \) as categories. The dashed arrows show the order between categories, rectangles contain members for each category and solid arrows represent the role \text{locIn}.

We define order constraints to encode dimensions.

**Definition 10.** For a simple role \( s \), an order constraint (along \( s \)) takes the form \( \text{ord}(s, \mathcal{A}, \prec) \), with \( \mathcal{A} \subseteq \mathbb{N}_c \) finite, and \( \prec \) a strict partial order over \( \mathcal{A} \). An interpretation \( \mathcal{I} \) satisfies \( \text{ord}(s, \mathcal{A}, \prec) \) if

\[
\begin{align*}
&\mathcal{I}(s) \subseteq \bigcup_{A_1, A_2 \in \mathcal{A}} (A_1^s \times A_2^s),
&\mathcal{I}(s) \cap \bigcup_{A_1, A_2 \in \mathcal{A}} (A_1^s \times A_2^s) = \emptyset.
\end{align*}
\]

Intuitively, whenever \( \text{ord}(s, \mathcal{A}, \prec) \) is satisfied in \( \mathcal{I} \), all objects connected by \( s \) are instances of \( \mathcal{A} \)-concepts, in a way that is compliant with the order \( \prec \). Further, \( s \)-paths connecting instances of concepts in \( \mathcal{A} \) which are incomparable w.r.t. \( \prec \) will be disallowed in \( \mathcal{I} \). The latter is important as otherwise one cannot guarantee \( k \)-boundedness.

**Example 4.** The Location dimension from Figure 1 is captured by \( K_e = (\mathcal{T}_e, \mathcal{A}_e) \) and the order constraint

\[
\begin{align*}
c = \text{ord}(\text{locIn}, \{\text{Venue}, \text{City}, \text{Country}\}, \prec)
\end{align*}
\]

with Venue \( \prec \) City \( \prec \) Country. In each model of \( K_e \) satisfying \( c \), the role \text{locIn} only connects instances of Venue with those of City or Country, and instances of City only with those of Country, thus capturing the intended semantics of the dimension. \( \triangle \)

**Definition 11.** A multi-dimensional KB is a triple \((\mathcal{T}, \mathcal{A}, \mathcal{C})\) where \((\mathcal{T}, \mathcal{A})\) is a recursion safe DL-Lite\(^{HR} \) KB and \( \mathcal{C} \) a set of order constraints.

We will show that for multi-dimensional KBs providing certain guarantees w.r.t. \( \mathcal{C} \), there is a \( k \) that ensures \( k \)-boundedness and allows construction of a \( k \)-unfolding of \( \mathcal{T} \).

**Definition 12.** \( \mathcal{C} \) covers a role \( r \) in \( \mathcal{T} \) if there exists a partial order \((\mathcal{A}, \prec)\) such that for every role \( s \) in the set \( \{ s \mid r \cdot s \subseteq r \in \mathcal{T} \} \), \( \text{ord}(s, \mathcal{A}, \prec) \subseteq \mathcal{C} \) for some \( \mathcal{A} \subseteq \mathcal{A}' \). We say that \( \mathcal{C} \) covers \( \mathcal{T} \), if it covers every role \( r \) in \( \mathcal{T} \).

Further, \((\mathcal{T}, \mathcal{A})\) is \( \mathcal{C} \)-admissible if \( \mathcal{E}_{\mathcal{T}, \mathcal{A}} \) satisfies each \( c \in \mathcal{C} \).

For example, the singleton set containing the order constraint \( c \) of Example 4 covers \( \mathcal{T}_e \), and \( K_e \) is \{\( c \}\)-admissible since \( \mathcal{E}_{\mathcal{T}_e, \mathcal{A}_e} \) satisfies \( c \).

**Lemma 3.** Let \((\mathcal{T}, \mathcal{A})\) be a recursion-safe DL-Lite\(^{HR} \) KB, and let \( \mathcal{C} \) be a set of order constraints covering \( \mathcal{T} \). If \((\mathcal{T}, \mathcal{A})\) is \( \mathcal{C} \)-admissible, then \( \mathcal{A} \) is \( \ell(\mathcal{C}) \)-bounded for \( \mathcal{T} \), where \( \ell(\mathcal{C}) := \max\{|\mathcal{A}| \mid \text{ord}(s, \mathcal{A}, \prec) \subseteq \mathcal{C}\} \).

Lemma 3 together with Theorem 4 yield FO-rewritability of queries over multi-dimensional KBs.

**Theorem 5.** Let \( \mathcal{T} \) be a recursion safe DL-Lite\(^{HR} \) TBox, \( \mathcal{C} \) a set of order constraints that covers \( \mathcal{T} \), and \( q \) a CQ. Let \( Q \) be the \( \ell(\mathcal{C}) \)-rewriting of \( q \) w.r.t. \( \mathcal{T} \). Then, for each ABox \( \mathcal{A} \) such that \((\mathcal{T}, \mathcal{A})\) is \( \mathcal{C} \)-admissible,

\[
\text{cert}(q, \mathcal{T}, \mathcal{A}) = \bigcup_{q' \in Q} \text{cert}(q', \emptyset, \mathcal{A}).
\]

Finally, we note that \( \mathcal{C} \)-admissibility amounts to evaluating simple queries on \( \mathcal{E}_{\mathcal{T}, \mathcal{A}} \). This can be done in time that is polynomial in \( \mathcal{C} \), \( \mathcal{T} \), and \( \mathcal{A} \). Moreover, although testing \( \mathcal{C} \)-admissibility is data dependent, once it is established, FO-rewritability is guaranteed for any CQ.

**Proposition 4.** Checking \( \mathcal{C} \)-admissibility for recursion safe DL-Lite\(^{HR} \) KBs is feasible in polynomial time in combined complexity.

**Reformulations for Dimensional Navigation**

The multi-dimensional data model enables data navigation along different axes given by the dimensions, similarly to points in a multi-dimensional space. This view lies at the core of OLAP and similar data analytic applications. For instance, using dimension Location, we can navigate from events occurring in some city to those occurring in some country, or in some venue. This navigation mechanism allows users to either zoom in or zoom out on the particular data, and it is usually realized by the so-called drill-down and roll-up operators.

In our setting we can define similar navigation mechanisms for multi-dimensional KBs. We do this by means of queries containing an ‘entry point’ to some dimension,
represented by some order constraint. A CQ $q$ refers to $(T, A, C)$ if there are $\text{ord}(s, A, <) \in C$, $r \cdot s \sqsubseteq r \in T$ and $A \in A$ such that one of the following conditions is satisfied:

1. $\{r(x, y), A(y)\} \sqsubseteq q$ or
2. $\{r(x, y), y = a\} \sqsubseteq q$ and $(T, A) \models A(a)$

where $y$ is a non-answer variable which does not occur elsewhere in $q$.

We now define our version of the roll-up and drill-down operators. We restrict their application to coherent KBs where paths along the dimension exist. A multi-dimensional KB $(T, A, C)$ is coherent if $C$ covers $T$, $(T, A)$ is C-admissible and for each $\text{ord}(s, A, <) \in C$ and each $A \in A$ such that there is some $A' \in A$ with $A < A'$ we have $A(x) \sqsubseteq_{C} \exists s(x)$.

\textbf{Definition 13} (Roll-up, drill-down). Let $(T, A, C)$ be a coherent multi-dimensional KB, $q$ a CQ that refers to $(T, A, C)$, and $\Gamma \subseteq q$ the set of atoms witnessing this.

A roll-up of $q$ w.r.t. $\Gamma$ is a CQ obtained by applying a substitution $\theta_r$, on $q$, and a drill-down of $q$ w.r.t. $\Gamma$ is a CQ obtained by applying substitution $\theta_d$ on $q$, where $\theta_r, \theta_d$ are as follows:

- $\theta_r = [A(x)/B(x)]$, if $A(x) \in \Gamma$, $A \prec B$ in some $c \in C$;
- $\theta_r = [x = a/x = b]$ if $x = a \in \Gamma$ and $(T, A) \models s(a, b)$;
- $\theta_d = [A(x)/B(x)]$, if $A(x) \in \Gamma$, $B \prec A$ in some $c \in C$;
- $\theta_d = [x = a/x = b]$, if $x = a \in \Gamma$ and $(T, A) \models s(b, a)$.

\textbf{Example 5.} Consider the KB $K_c$ and order constraint $c$ as in Example 4. We have that $(K_c, \{c\})$ is coherent. Now, consider the following set of queries:

\begin{align*}
q_1(x) &\leftarrow \text{Event}(x), \text{occIn}(x, y), \text{City}(y); \\
q_1^r(x) &\leftarrow \text{Event}(x), \text{occIn}(x, y), \text{Country}(y); \\
q_1^d(x) &\leftarrow \text{Event}(x), \text{occIn}(x, y), \text{Venue}(y).
\end{align*}

The fact that $q_1$ refers to $(K_c, \{c\})$ is witnessed by the atoms $\Gamma_1 = \{\text{occIn}(x, y), \text{City}(y)\}$. Since $\text{City} \prec \text{Country}$ in $c$, $q_1^r$ is a roll-up of $q_1$ w.r.t. $\Gamma_1$, and since $\text{Venue} \prec \text{City}$ in $c$, $q_1^d$ is a drill-down of $q_1$. Now, consider the following queries:

\begin{align*}
q_2(x) &\leftarrow \text{Event}(x), \text{occIn}(x, y), y = \text{Vienna}; \\
q_2^r(x) &\leftarrow \text{Event}(x), \text{occIn}(x, y), y = \text{Austria}; \\
q_2^d(x) &\leftarrow \text{Event}(x), \text{occIn}(x, y), y = \text{StOpera}.
\end{align*}

The fact that $q_2$ refers to $(K_c, \{c\})$ is witnessed by the atoms $\Gamma_2 = \{\text{occIn}(x, y), y = \text{Vienna}\}$ and using $K_c \models \text{locIn}(\text{Vienna, Austria})$ and $K_c \models \text{locIn}(\text{StOpera, Vienna})$ we get that $q_2^r$ is a roll-up of $q_2$ w.r.t. $\Gamma_2$ and $q_2^d$ is a drill-down of $q_2$ w.r.t. $\Gamma_2$.

For coherent multi-dimensional KBs, the roll-up operation can be seen as a sequence of relaxing rules, and similarly, drill-down can be seen as a sequence of restrictings. Let $q$ be a CQ that refers to a coherent $(T, A, C)$. If $q_r$ is a roll-up of $q$ w.r.t. $\{r(x, y), A(y)\}$, then $q_r$ can be obtained as follows:

1. Coherence guarantees that GD2 can be applied, obtaining query $q'$ by replacing $A(y) \in q$ with $s(y, z), B(z)$, where $z$ is a fresh variable; due to C-admissibility it must be that $A \prec B$.

2. Since $q$ refers to $(T, A, C)$ we have that $r \cdot s \sqsubseteq r \in T$ and $r(x, y) \in q'$ with $y$ not occurring elsewhere in $q'$. Thus we can apply G6 on $q'$ to obtain $q_r$.

Like-wise, if $q_r$ is a roll-up of $q$ w.r.t. $\{r(x, y), y = a\}$, then $q_r$ can be obtained as follows:

1. Since $q$ refers to $(T, A, C)$ it must be that $(T, A) \models A(a)$, for some $A$ in some order constraint in $C$; coherence ensures that there exists $b \in \text{ind}(A)$ such that $(T, A) \models s(a, b)$, therefore we can apply GA3 to obtain query $q'$ by replacing $y = a$ with $s(y, z), z = b$, where $z$ is a fresh variable.

2. Next, again we can apply G6 as above and obtain $q_r$.

For drill-down queries, we apply the dual rules in the reverse order. From this observation, we obtain:

\textbf{Proposition 5.} Let $(T, A, C)$ be a coherent multi-dimensional KB, $q$ a CQ that refers to $(T, A, C)$ and $\Gamma \subseteq q$ a subset of atoms witnessing this. We have that the following hold:

\begin{itemize}
\item[(r)] $q \subseteq (T, A) \models q_r$ for each roll-up $q_r$ of $q$ w.r.t. $\Gamma$,
\item[(d)] $q_d \subseteq (T, A) \models q_d$ for each drill-down $q_d$ of $q$ w.r.t. $\Gamma$.
\end{itemize}

\section*{Related Work}

Query reformulations based on similarity measures have been considered for RDF data and SPARQL queries by Reddy and Kumar (2010), Huang and Liu (2010) and Virgilio et al. (2013), whereas approaches using simple ontological knowledge for such task have been proposed by Hurtado, Poulovassilis and Wood (2008), Elbassuoni et al. (2011), Dogol et al. (2009) and Frosini et al. (2017). Relaxations of SQL queries in relational databases using concept taxonomies have been studied by Martinenghi and Torlone (2014). For cooperative KBs, Inoue and Wiese (2011) define relaxations of CQs following a principled logic-based approach. Interactive faceted search techniques implement effective drill-down for refining queries (Roy et al. 2008; Kashyap, Hristidis, and Petropolous 2010); in the context of RDF and knowledge graphs Arenas et al. (2016) and Sherkhonov et al. (2017) addressed theoretical underpinnings of faceted search for data/ontology exploration. Query evaluation minimizing data access in an OBDA under generalization/specialization relations is studied by Andresel, Ortiz and Simkus (2016).

Logic-based formalizations of the multi-dimensional data model of Hurtado and Mendelzon (2002) have been proposed in the literature. Franconi and Sattler (1999), and Franconi and Kambal (2004) use DLs for modeling and reasoning about multi-dimensional data without considering querying, while Bertossi and Milani (2018) rely on an expressive fragment of Datalog$^+$ to capture dimensional knowledge, although at the expense of higher complexity (i.e., not FO-rewritable).

Query answering using CRIs is supported in ontology mediated settings where the DL has CRIs, or the query language contains conjunctive regular path queries (see Ortiz (2013) and (Ortiz and Simkus (2012) for references)). However, query answering in all those settings is necessarily NLOGSPACE-hard in data complexity, and usually PSPACE-hard in combined complexity even for lightweight DLs (Bi-
envenu, Ortiz, and Šimkus 2015), while our goal in this paper is to design FO-rewritable DL-Lite extensions.

**Discussion and Conclusions**

We presented query reformulation rules that are data independent, as well as more fine-grained rules leveraging current dataset. To capture multi-dimensional knowledge, we extended DL-Lite with a restricted use of CRIs that preserve FO-rewritability, and yet cover the desired use case.

Our data-driven rules take into account a particular kind of dependencies in the data. We chose these somewhat subjectively, aiming at enhanced dimensional navigation, while keeping the complexity in check. Indeed, testing those dependencies in DL-Lite KBs consisting of a recursion safe TBox and a k-bounded ABox is not computationally expensive (AC0 in data complexity). Clearly, other approaches for data-driven reformulation might be feasible.

With the approach we have described there may be many possible reformulations of a given query, and not all of them are equally interesting. In our future research we will investigate relaxations/ restrictions that minimally modify the query answers, properties of our reformulation rules, and algorithms to effectively compute preferred reformulations. We are also investigating mechanisms for compiling the data and the ontology to support efficient answering of reformulated queries, and the definition of a declarative query language considering relaxing/restraining operators as first-class citizens. Finally, we also plan to consider aggregation and the definition of operators suitable for data analysis tasks in the spirit of OLAP systems.
