Abstract

In this paper, we advocate the use of setwise contests for aggregating a set of input rankings into an output ranking. We propose a generalization of the Kemeny rule where one minimizes the number of $k$-wise disagreements instead of pairwise disagreements (one counts 1 disagreement each time the top choice in a subset of alternatives of cardinality at most $k$ differs between an input ranking and the output ranking). After an algorithmic study of this $k$-wise Kemeny aggregation problem, we introduce a $k$-wise counterpart of the majority graph. It reveals useful to divide the aggregation problem into several sub-problems. We conclude with numerical tests.

1 Introduction

Rank aggregation aims at producing a single ranking from a collection of rankings of a fixed set of alternatives. In social choice theory (e.g., Moulin 1991), where the alternatives are candidates to an election and each ranking represents the preferences of a voter, aggregation rules are called Social Welfare Functions (SWFs). Apart from social choice, rank aggregation has proved useful in many applications, including preference learning (Cheng and Hüllermeier 2009; Clémençon, Korb, and Sibony 2018), collaborative filtering (Wang et al. 2014), genetic map creation (Jackson, Schnable, and Aluru 2008), similarity search in databases systems (Fagin, Kumar, and Sivakumar 2003) and design of web search engines (Altman and Tennenholtz 2008; Dwork et al. 2001).

In the following, we use interchangeably the terms “input rankings” and “preferences”, “output ranking” and “consensus ranking”, as well as “alternatives” and “candidates”.

The well-known Arrow’s impossibility theorem states that there exists no aggregation rule satisfying a small set of desirable properties (Arrow 1950). In the absence of an “ideal” rule, various aggregation rules have been proposed and studied. Following Fishburn’s classification (1977), we can distinguish between the SWFs for which the output ranking can be computed from the majority graph alone, those for which the output ranking can be computed from the weighted majority graph alone, and all other SWFs\(^1\). The majority graph is obtained from the input rankings by defining one vertex per alternative $c$ and by adding an edge from $c$ to $c'$ if $c$ is preferred to $c'$ in a strict majority of input rankings. In the weighted majority graph, each edge is weighted by the majority margin. The many SWFs that rely on these graphs alone take therefore only pairwise comparisons into account to determine an output ranking. For a compendium of these SWFs, we refer to the book by Brandt et al. (2016).

The importance of this class of SWFs can be explained by their connection with the Condorcet consistency property, stating: if there is a Condorcet winner (i.e., an alternative with outgoing edges to every other ones in the majority graph), then it should be ranked first in the output ranking. Nevertheless, as shown by Baldiga and Green (2013), the lack of Condorcet consistency is not necessarily a bad thing, because this property may come into contradiction with the objective of maximizing voters’ agreement with the output ranking. The following example illustrates this point.

Example 1 (Baldiga and Green, 2013). Consider an election with 100 voters and 3 candidates $c_1, c_2, c_3$, where 49 voters have preferences $c_1 \succ c_2 \succ c_3$, 48 have preferences $c_3 \succ c_2 \succ c_1$ and 3 have preferences $c_2 \succ c_3 \succ c_1$. Candidate $c_2$ is the Condorcet winner, but is the top choice of only 3 voters. In contrast, candidate $c_1$ is in slight minority against $c_2$ and $c_3$, but $c_1$ is the top choice of 49 voters. This massive gain in agreement may justify to put $c_1$ instead of $c_2$ in first position of the output ranking.

Following Baldiga and Green (2013), we propose to handle this tension between the pairwise comparisons (leading to ranking $c_2$ first) and the plurality choice (leading to ranking $c_1$ first) by using SWFs that take into account not only pairwise comparisons but setwise contests. More precisely, given input rankings on a set $C$ of candidates and $k \in \{2, \ldots, |C|\}$, the idea is to consider the plurality score of each candidate $c$ for each subset $S \subseteq C$ such that $2 \leq |S| \leq k$, where the plurality score of $c$ for $S$ is the number of voters for which $c$ is the top choice in $S$. The results of setwise con-

---

\(^{1}\)Fishburn’s classification actually applies to social choice functions, which prescribe a subset of winning alternatives from a collection of rankings, but the extension to SWFs is straightforward.

2 Preliminaries

Adopting the terminology of social choice theory, we consider an election with a set \( V \) of \( n \) voters and a set \( C \) of \( m \) candidates. Each voter \( v \) has a complete and transitive preference order \( r_v \) over candidates (also called ranking). The collection of these rankings defines a preference profile \( \mathcal{P} \).

Notations and Definitions

Let us introduce some notations related to rankings. We denote by \( \mathcal{R}(C) \) the set of \( m! \) rankings over \( C \). Given a ranking \( r \) and two candidates \( c \) and \( c' \), we write \( c \succ_ r c' \) if \( c \) is in a higher position than \( c' \) in \( r \). Given a ranking \( r \) and a candidate \( c \), \( \text{rk}(c,r) \) denotes the rank of \( c \) in \( r \). For instance, \( \text{rk}(c,r_v) = 1 \) if \( c \) is the preferred candidate of voter \( v \) (the candidate ranked highest in \( r_v \)).

A natural SWF in this class consists in determining an output ranking that minimizes the number of disagreements with the results of setwise contests for sets of cardinality at most \( k \). This is a \( k \)-wise generalization of the Kemeny rule, obtained as a special case for \( k=2 \). We recall that the Kemeny rule consists in producing a ranking that minimizes the number of pairwise disagreements (Kemeny 1959).

**Example 2.** Let us come back to Example 1 and assume that we use the 3-wise Kemeny rule. Consider the output ranking \( r = c_1 > c_2 > c_3 \). For set \( S = \{c_1, c_2\} \), the number of disagreements with the results of setwise contests is 51 because \( c_2 \) is the top choice in \( S \) for 51 voters (see Table 1) while it is \( c_1 \) for \( r \). Similarly, the number of disagreements induced by \( \{c_1, c_3\} \), \( \{c_2, c_3\} \) and \( \{c_1, c_2, c_3\} \) are respectively 51, 48 and 3+48. The total number of disagreements is thus 51+51+48+3+48=201. This is actually the minimum number of disagreements that can be achieved for these input rankings, which makes \( r \) the \( k \)-wise Kemeny ranking.

The purpose of this paper is to study the \( k \)-wise Kemeny aggregation problem. Section 2 formally defines the problem and reports on related work. Section 3 is devoted to some axiomatic considerations of the corresponding voting rule, and to an algorithmic study of the problem. We then investigate a \( k \)-wise variant of the majority graph in Section 4. We prove that determining this graph is easy for \( k = 3 \) but becomes NP-hard for \( k > 3 \), and we show how to use it in a preprocessing step to speed up the computation of the output ranking. Numerical tests are presented in Section 5. Due to lack of space, missing proofs can be found in the long version of the paper (Gilbert, Portoleau, and Spanjaard 2019).
have $\delta^2_{KT} = \delta_{KT}$. Thirdly and maybe most importantly, we point out that the distances induced by $\delta^k_{KT}(r, r')$ can be computed in $O(m^3)$ by using the following formula:

$$\delta^k_{KT}(r, r') = \sum_{c,c' \subseteq C} \mathbb{1}_{c \succ_r c'} \mathbb{1}_{c' \succ_r r} \Delta^{k-2}(B_c(r) \cap B_{c'}(r'))$$

$$\sum_{c,c' \subseteq C} \mathbb{1}_{c \succ_r c'} \mathbb{1}_{c' \succ_r r} \sum_{i=0}^{k-2} \binom{\Delta^{k-2}(B_c(r) \cap B_{c'}(r'))}{i}$$

(1)

where $B_c(r) = \{ x \in C \text{ s.t. } c \succ_r x \}$ is the set of candidates that are ranked below $c$ in $r$. Let us give some intuition for this formula. For any pair $\{c, c'\}$ of candidates such that $c \succ_r c'$ and $c' \succ_r c$, we count the number of sets in $\Delta^k$ on which there is a disagreement because the top choice is $c$ for $r$ while it is $c'$ for $r'$. Such sets are of the form $S \cup \{c, c'\}$, where $S \in \Delta^{k-2}(B_c(r) \cap B_{c'}(r'))$, otherwise $c$ and $c'$ would not be the top choices. Hence the formula.

The distance $\delta_{KT}$ induces a new SWF, the $k$-wise Kemeny rule, which, given a profile $P$, returns a ranking $r$ with minimal distance $\delta^k_{KT}$ to $P$, where:

$$\delta^k_{KT}(r, P) = \sum_{r' \in P} \delta^k_{KT}(r, r')$$

Note that this coincides with the rule we used in the introduction, by commutativity of addition:

$$\sum_{r' \in P} \sum_{S \in \Delta^k} \mathbb{1}_{t_r(S) \neq t_{r'}(S)} = \sum_{S \in \Delta^k} \sum_{r' \in P} \mathbb{1}_{t_r(S) \neq t_{r'}(S)}$$

Determining a consensus ranking for this rule defines the $k$-wise Kemeny Aggregation Problem ($k$-KAP for short).

**k-WISE KEMENY AGGREGATION PROBLEM**

**INSTANCE:** A profile $P$ with $n$ voters and $m$ candidates.

**SOLUTION:** A ranking $r$ of the $m$ candidates.

**MEASURE:** $\delta^k_{KT}(r, P)$ to minimize.

### Related Work

Several other variants of the Kemeny rule have been proposed in the literature, either to obtain generalizations able to deal with partial or weak orders (Dwork et al. 2001; Zwicker 2018), to penalize more some pairwise disagreements than others (Kumar and Vassilvitskii 2010), or to account for candidates that may become unavailable after voters express their preferences (Baldiga and Green 2013; Lu and Boutilier 2010).

Indeed, despite its popularity, the Kemeny rule has received several criticisms. One of them is that the Kendall tau distance counts equally the disagreements on every pair of candidates. This property is undesirable in many settings. For instance, with a web search engine, a disagreement on a pair of web pages with high positions in the considered rankings should have a higher cost than a disagreement on pairs of web pages with lower ones. This drawback motivated the introduction of weighted Kendall tau distances by Kumar and Vassilvitskii (2010). A more thorough comparison between our work and theirs can be found in the extended version of the paper (Gilbert, Porteau, and Spanjaard 2019).

Let us illustrate with the following example, that the $k$-wise Kendall tau distance is also well suited to penalize more the disagreements involving alternatives at the top of the input rankings.

**Example 3.** Consider rankings $r_1, r_2, r_3$ defined by $c_1 \succ c_2 \succ r_1 c_3, c_1 \succ r_2 c_3 \succ r_2 c_2$, and $c_2 \succ r_3 c_1 \succ r_3 c_3$. We have $\delta_{KT}(r_1, r_2) = \delta_{KT}(r_1, r_3) = 1$ while $\delta_{KT}(r_1, r_2) = 1 < 2 = \delta_{KT}(r_1, r_3)$ because $r_1$ and $r_3$ disagree on both subsets $\{c_1, c_2\}$ and $\{c_1, c_2, c_3\}$. Put another way, $\delta_{KT}(r_1, r_3) > \delta_{KT}(r_1, r_2)$ because $r_1$ and $r_3$ disagree on their top-ranked alternatives whereas $r_1$ and $r_2$ disagree on the alternatives ranked in the last places.

The two works closest to ours are related to another extension of the Kemeny rule. This extension considers a setting in which, besides the fact that voters have preferences over a set $C$, the election will in fact occur on a subset $S \subseteq C$ drawn according to a probability distribution (Baldiga and Green 2013; Lu and Boutilier 2010). The optimization problem considered is then to find a consensus ranking $r$ which minimizes, in expectation, the number of voters’ disagreements with the chosen candidate in $S$ (a voter $v$ disagrees if $t_v(S) \neq t_r(S)$). The differences between the work of Baldiga and Green (2013) and the one of Lu and Boutilier (2010) is then twofold. Firstly, while Baldiga and Green mostly focused on the axiomatic properties of this aggregation procedure, the work of Lu and Boutilier has more of an algorithmic flavor. Secondly, while Baldiga and Green mostly study a setting in which the probability $P(S)$ of $S$ is only dependent on its cardinality (i.e., $P(S)$ is only a function of $|S|$), Lu and Boutilier study a setting that can be viewed as a special case of the former, where each candidate is absent of $S$ independently of the others with a probability $p$ (i.e., $P(S) = p^{C\setminus S}(1-p)^{|S|}$). The Kemeny aggregation problem can be formulated in both settings, either by defining $P(S) = 0$ for $|S| \geq 3$, or by defining a probability $p$ that is “sufficiently high” w.r.t. the size of the instance (Lu and Boutilier 2010). Lu and Boutilier conjectured that the determination of a consensus ranking is NP-hard in their setting, designed an exact method based on mathematical programming, two approximation greedy algorithms and a PTAS.

Our model can be seen as a special case of the model of Baldiga and Green where the set $S$ is drawn uniformly at random within the set of subsets of $C$ of cardinal smaller than or equal to a given constant $k \geq 2$. While it cannot be casted in the specific setting studied by Lu and Boutilier, our model is closely related and may be used to obtain new insights on their work.

### 3 Aggregation with the k-wise Kemeny Rule

In this section, we investigate the axiomatic properties of the $k$-wise Kemeny rule, and then we turn to the algorithmic study of $k$-KAP.

**Axiomatic Properties of the k-wise Kemeny Rule**

Several properties of the $k$-wise Kemeny rule have already been studied by Baldiga and Green (2013), because their setting includes the $k$-wise Kemeny rule as a special case.
Among other things, they showed that the rule is not Condorcet consistent. That is to say, a Condorcet winner may not be ranked first in any consensus ranking even when one exists, as illustrated by Example 2.

The authors also show that the k-wise Kemeny rule is neutral, i.e., all candidates are treated equally, and that for $k \geq 3$ it is different from any positional method or any method that uses only the pairwise majority margins (among which is the standard Kemeny rule). We provide here some additional properties satisfied by the k-wise Kemeny rule:

- **Monotonicity**: up-ranking cannot harm a winner; down-ranking cannot enable a loser to win.
- **Unanimity**: if all voters rank $c$ before $c'$, then $c$ is ranked before $c'$ in any consensus ranking.
- **Reinforcement**: let $\mathcal{R}_P^+$ and $\mathcal{R}_P^-$ denote the sets of consensus rankings for preference profiles $\mathcal{P}$ and $\mathcal{P}'$ respectively. If $\mathcal{R}_P^+ \cap \mathcal{R}_P^- \neq \emptyset$ and $\mathcal{P}'$ is the profile obtained by concatenating $\mathcal{P}$ and $\mathcal{P}'$, then $\mathcal{R}_P^+ = \mathcal{R}_P^+ \cap \mathcal{R}_P^-$. Besides, the k-wise Kemeny rule does not satisfy Independence of irrelevant alternatives, i.e., the relative positions of two candidates in a consensus ranking can depend on the presence of other candidates. Let us illustrate this point with the following example.

**Example 4.** Considering the preference profile from Example 1, the only consensus ranking for $\delta^k_{\text{KT}}$ is $c_1 \succ c_2 \succ c_3$. Yet, without $c_3$ the only consensus ranking would be $c_2 \succ c_1$.

Lastly, note that there exists a noise model such that the k-wise Kemeny rule can be interpreted as a maximum likelihood estimator (Conitzer, Rognlie, and Xia 2009). In this view of voting, one assumes that there exists a “correct” ranking $r$, and each vote corresponds to a noisy perception of this correct ranking. Consider the conditional probability measure $\mathcal{P}$ on $\mathcal{R}(C)$ defined by $\mathbb{P}(r'|r) \propto e^{-\delta^k_{\text{KT}}(r,r')}$.

It is easy to convince oneself that the k-wise Kemeny rule returns a ranking $r^*$ that maximizes $\mathbb{P}(r^*) = \prod_{r', \in \mathcal{P}} \mathbb{P}(r^*)$ and is thus a maximum likelihood estimate of $r$.

**Computational Complexity of k-KAP**

We now turn to the algorithmic study of k-KAP. After providing a hardness result, we will design an efficient Fixed Parameter Tractable (FPT) algorithm for parameter $m$.

While k-KAP is obviously NP-hard for $k = 2$ as it then corresponds to determining a consensus ranking w.r.t. the Kemeny rule, we strengthen this result by showing that it is also NP-hard for any constant value $k \geq 3$. The proof, uses a reduction from 2-KAP.

**Theorem 1.** For any constant $k \geq 3$, k-KAP is NP-hard, even if the number of voters equals 4 or if the average range of candidates equals 2 (where the range of a candidate $c$ is defined by $\max_{r \in \mathcal{P}} r(c, r) - \min_{r \in \mathcal{P}} r(c, r) + 1$ and the average is taken over all candidates).

Despite this result, k-KAP is obviously FPT w.r.t. the number $m$ of candidates, by simply trying the $m!$ rankings in $\mathcal{R}(C)$. We now design a dynamic programming procedure which significantly improves this time complexity.

**Proposition 1.** If $r^*$ is an optimal ranking for k-KAP, then $\delta^k_{\text{KT}}(r^*, \mathcal{P}) = d^k_{\text{KT}}(C)$, where, for any subset $S \subseteq C$, $d^k_{\text{KT}}(S)$ is defined by the recursive relation:

$$
    d^k_{\text{KT}}(S) = \min_{c \in S} |d^k_{\text{KT}}(S \setminus \{c\}) + \sum_{r \in \mathcal{P}_S} \sum_{c' \succ_r c} \left( |S| - r(c', r) - 1 \right) | \tag{2}
$$

and $d^k_{\text{KT}}(\emptyset) = 0$.

**Proof.** Given $S \subseteq C$ and $c \in S$, let us define $\mathcal{R}_c(S)$ as $\{ r \in \mathcal{R}(S) \text{ s.t. } t_r(S) = c \}$. The set $\Delta^k_c(S)$ can be partitioned into $\Delta^k_c(S) = \{ S' \subseteq \Delta^k_c(S) \text{ s.t. } c \in S' \}$ and $\Delta^k_c(S) = \{ S' \subseteq \Delta^k(S) \text{ s.t. } c \notin S' \} = \Delta^k(S \setminus \{c\})$. Given a preference profile $\mathcal{P}$ over $C$ and a ranking $r \in \mathcal{R}_c(S)$, the summation defining $d^k_{\text{KT}}(r, \mathcal{P}_S)$ breaks down as follows:

$$
    d^k_{\text{KT}}(r, \mathcal{P}_S) = \sum_{r \in \mathcal{P}_S} \sum_{S' \subseteq \Delta^k(S)} \mathbb{I}_{t_r(S') \neq t_r(S')} = \delta^k_{\text{KT}}(r, \mathcal{P}_S) + \sum_{r \in \mathcal{P}_S} \sum_{S' \subseteq \Delta^k(S)} \mathbb{I}_{t_r(S') \neq t_r(S')} \tag{3}
$$

Using the same reasoning as in Equation 1 on page 1984, the second summand in Equation 3 can be rewritten as follows:

$$
    \sum_{r \in \mathcal{P}_S} \sum_{S' \subseteq \Delta^k(S)} \sum_{c \succ r, c} \left( |S| - r(c', r) - 1 \right) = \delta^k_{\text{KT}}(r, \mathcal{P}_S) + \sum_{r \in \mathcal{P}_S} \sum_{S' \subseteq \Delta^k(S)} \sum_{c \succ r, c} \left( |S| - r(c', r) - 1 \right) \tag{4}
$$

Consider now a ranking $r^* \in \mathcal{R}(S)$ such that $\delta^k_{\text{KT}}(r^*, \mathcal{P}_S) = \min_{c \in \mathcal{R}(S)} \delta^k_{\text{KT}}(r, \mathcal{P}_S)$. We have:

$$
    \delta^k_{\text{KT}}(r^*, \mathcal{P}_S) = \min_{c \in S} \min_{r \in \mathcal{R}(S)} \delta^k_{\text{KT}}(r, \mathcal{P}_S) = \min_{c \in S} \left( \min_{r \in \mathcal{R}(S \setminus \{c\})} \delta^k_{\text{KT}}(r, \mathcal{P}_S) \right) \tag{5}
$$

because the second summand in Equation 4 does not depend on $r$ (it only depends on $c$, which is the argument of the first min operator). If one denotes $\min_{c \in \mathcal{R}(S)} \delta^k_{\text{KT}}(r, \mathcal{P}_S)$ by $d^k_{\text{KT}}(S)$, one obtains Equation 2. This concludes the proof.

A candidate $c \in S$ that realizes the minimum in Equation 2 can be ranked in first position in an optimal ranking for $\mathcal{P}$. Once $d^k_{\text{KT}}(S)$ is computed for each $S \subseteq C$, a ranking $r^*$ achieving the optimal value $d^k_{\text{KT}}(C)$ can thus be determined recursively starting from $S = C$. The complexity of the induced dynamic programming method is $O(2^m m^2 n)$ as there are $2^m$ subsets $S \subseteq C$ to consider and each value.
The $k$-Wise Majority Digraph

We now propose and investigate a $k$-wise counterpart of the pairwise majority digraph, that will be used in a preprocessing procedure for $k$-KAP.

As stated in the introduction, the pairwise Kemeny rule is strongly related to the pairwise majority digraph. We denote by $G_P$ the pairwise majority digraph associated to profile $P$. We recall that in this digraph, there is one vertex per candidate, and there is an arc from candidate $c$ to candidate $c'$ if a strict majority of voters prefers $c$ to $c'$. In the weighted pairwise majority digraph, each arc $(c, c')$ is weighted by $w_P(c, c') := \{r \in P \mid c > r > c'\} - \{r \in P \mid c' > r > c\}$. The pairwise majority digraph $G_P$ is on the left of Figure 1.

![Figure 1: $k$-wise majoritgy digraph in Example 5 for $k=2$ (left) and $k=3$ (right).](image)

From $G_P$, we can define a set of consistent rankings:

**Definition 1.** Let $G$ be a digraph whose vertices correspond to the candidates in $C$. Let $B_1(G), \ldots, B_t(G)$ be the subsets of $C$ corresponding to the Strongly Connected Components (SCCs) of $G$, and $O(G)$ denote the set of linear orders $<_G$ on $\{1, \ldots, t(G)\}$ such that there exists an arc $(c, c')$ from $c \in B_i(G)$ to $c' \in B_j(G)$ if and only if $i < j$. Given $<_G \in O(G)$, we say that a ranking $r$ is consistent with $<_G$ if the candidates in $B_1$ are ranked before the ones of $B_2$ when $i < j$.

The following result states that, for any $<_G \in O(G)$, there exists a consensus ranking for $\delta_{ST}$ among the rankings consistent with $<_G$.

**Theorem 2** (Theorem 16 in reference Charon and Hudry, 2010). Let $P$ be a profile over $C$ and assume that the SCCs of $G_P$ are numbered according to a linear order $<_G \in O(G_P)$. Consider the ranking $r^*$, consistent with $<_G$, obtained by the concatenation of rankings $r_1, \ldots, r_t(G_P)$ where $\delta_{ST}(r_i^*, P_{B_i(G_P)}) = \min_{r \in R(B_i(G_P))} \delta_{ST}(r, P_{B_i(G_P)})$. We have:

$$\delta_{ST}(r^*, P) = \min_{r \in R(C)} \delta_{ST}(r, P)$$

That is, $r^*$ is a consensus ranking according to the Kemeny rule. Furthermore, if $O(G_P) = \{<_G\}$ and $w_P(c, c') > 0$ for all $c \in B_i(G_P)$ and $c' \in B_j(G_P)$ when $i < j$, then all consensus rankings are consistent with $<_G$.

This result does not hold anymore if one uses $\delta_{ST}$ (with $k \geq 3$) instead of $\delta_{ST}$, as shown by the following example.

**Example 6.** Let us denote by $P$ the profile of Example 1. The pairwise majority digraph $G_P$ has three SCCs $B_1(G_P) = \{c_2\}$, $B_2(G_P) = \{c_3\}$ and $B_3(G_P) = \{c_1\}$. In this example, $O(G(P)) = \{<_G\}$ where $1 < _G 2 < _G 3$. The only ranking consistent with $<_G$ is $c_2 > c_3 > c_1$ while the only consensus ranking w.r.t. the 3-wise Kemeny rule is $c_1 > c_2 > c_3$.

In order to adapt Theorem 2 to the $k$-wise Kemeny rule, we now introduce the concept of $k$-wise majority digraph. Let $\Delta^k_{cc}(S) = \{S' \in \Delta^k_c(S) \mid \forall i \in S, c_i \subseteq S'\}$. If $S$ is not specified, it is assumed to be $C$. Given a ranking $r$, we denote by $\Delta^k_{cc}(S, c, c')$ the set $\{S' \in \Delta^k_{cc}(S) \mid \forall i \in S, c_i \cap c' \neq \emptyset\}$. Given a profile $P$, we denote by $\phi^k_P(S, c, c')$ the value $\sum_{r \in P} \Delta^k_{cc}(S, c, c')$ and by $w^k_P(S, c, c')$ the difference $\phi^k_P(S, c, c') - \phi^k_P(S, c, c')$. This definition implies that $w^k_P(S, c, c')$ is the net agreement loss that would be incurred by swapping $c$ and $c'$ in a feasible solution $r$ of $k$-KAP where $r(k(c', r) \neq r(k(c, r) \neq 1)$ and $S = B(r) \cup \{c, c'\}$. If $max_{S \in \Delta^m_{cc}} w^k_P(S, c, c') > 0$ (resp. min$_{S \in \Delta^m_{cc}} w^k_P(S, c, c') > 0$) then, in a consensus ranking $r$ for $\delta^k_{ST}$ where $c$ and $c'$ would be consecutive, it is possible (resp. necessary) that $c > r c'$.

The $k$-wise majority digraph associated to a profile $P$ over a set $C$ of candidates is the weighted digraph $G^k_P = (V, A)$, where $V = C$ and $(c, c') \in A$ if:

$$\exists S \in \Delta^m_{cc}\ s.t. \ w^k_P(S, c, c') > 0.$$  

The weight $w^k_P(S, c, c')$ of this arc is then given by:

$$w^k_P(c, c') := \max_{S \in \Delta^m_{cc}} w^k_P(S, c, c').$$

Note that, if $k \geq 3$, we may obtain edges $(c, c')$ and $(c', c)$ both with strictly positive weights (which is impossible in the pairwise majority digraph). For instance, for the profile $P$ of Example 5, $w^k_P(c_2, c_3) = w^k_P(c_2, c_3, c_4) = 1$ and $w^k_P(c_4, c_3) = w^k_P(c_4, c_3, c_5) = 4$. The digraph $G^2_P$ is shown on the right of Figure 1. Besides, for any $P$, $G^2_P$ is the pairwise majority digraph as $\Delta^2_{cc}(S) = \{\{c, c'\}\} \forall S \in \Delta^m_{cc}$. Theorem 2 adapts as follows for an arbitrary $k$:

**Theorem 3.** Let $P$ be a profile over $C$ and assume that the SCCs of $G^k_P$ are numbered according to a linear order $<_G \in O(G^k_P)$. Among the rankings consistent with $<_G$, there exists a consensus ranking w.r.t. the $k$-wise Kemeny rule. Besides, if $O(G^k_P) = \{<_G\}$ and $\min_{S \in \Delta^m_{cc}} w^k_P(S, c, c') > 0$ for all $c \in B_i(G^k_P)$ and $c' \in B_j(G^k_P)$ when $i < j$, then all consensus rankings are consistent with $<_G$.
Figure 2: The meta-graph of SCCs of $G^3_p$ in Example 5.

Example 7. The meta-graph of SCCs of $G^3_p$ in Example 5 is represented in Figure 2. The above result implies that there exists a consensus ranking among $c_1 > c_2 > c_3 > c_4 > c_5 > c_6$, $c_1 > c_2 > c_3 > c_4 > c_5 > c_6$, and $c_1 > c_2 > c_3 > c_4 > c_5 > c_6$. The above result implies that there exists a consensus ranking consistent with $\prec \in O(G^3_p)$, and then 2) to work on each SCC separately, before concatenating the obtained rankings. However, for a consensus ranking consistent with $\prec \in G^3_p$, the relative positions of candidates in $G'_i(G^3_p)$ depend on the set of candidates in $B_{g+1}(G^3_p) := B_{g+1}(G^3_p)$ (not on their order). The influence of $B_{g+1}(G^3_p)$ can be captured in the dynamic programming procedure by applying a modified version of Equation 2 separately for each subset $B_{g+1}(G^3_p)$ down to $B_1(G^3_p)$. Formally, if $r^*$ is optimal for $k$-KAP, then:

$$d^k_{PT}(G^3_p) = \sum_{i=1}^t d^k_{PT}(B_i(G^3_p))$$

where, for any subset $S \subseteq B_i(G^3_p)$, $d^k_{PT}(S)$ is defined by $d^k_{PT}(\emptyset) = 0$ and $(B_{g+1} \cup \ldots \cup B_{g+1}(G^3_p))$ (but not on their order).

Example 8. Let us refine the digraph $G^3_p$ previously obtained for the profile $P$ of Example 5. The SCCs are $B_1 = \{c_1\}, B_2 = \{c_2\}, B_3 = \{c_3, c_4\}$ and $B_4 = \{c_5, c_6\}$ and $O(G^3_p) = \{\prec \in G^3_p\}$, where $1 < \prec 2 < \prec 3 < \prec 4$. A set maximizing $w^3_p(S, c, c')$ is $S = \{c_2, c_3, c_4\}$. This set contains $c_2$ while it is necessarily above $c_3$ in a consistent ranking. Conversely, candidates $c_5$ and $c_6$ are omitted while they are necessarily below $c_3$. By taking into account these constraints, we obtain that a set maximizing $w^3_p(S, c, c')$ is $S = \{c_3, c_4, c_5, c_6\}$. For which $w^3_p(S, c, c') = -4$. Hence, we can remove the arc $(c_3, c_4)$ from $G^3_p$. Similarly, it is possible to show that the arc $(c_5, c_6)$ can be removed from $G^3_p$.

5 Numerical Tests

Our numerical tests have three objectives: we evaluate the computational performance of the dynamic programming approach of Section 3, we evaluate the impact of parameter $k$ on the set of consensus rankings, and we assess the efficiency of the preprocessing technique of Section 4.

Generation of preference profiles. The preference profiles are generated according to the Mallows model (Mallows 1957), using the Python package PrefLib-Tools (Mattei and Walsh 2013). This model takes two parameters as input: a reference ranking $\sigma$ (the mode of the distribution) and a dispersion parameter $\phi \in (0, 1)$. Given these inputs, the probability of generating a ranking $r$ is proportional to $\phi^{\text{dist}(r, \sigma)}$. The more $\phi$ tends towards 0 (resp. 1), the more the preference rankings become correlated and resemble $\sigma$ (resp. become equally probable, i.e., we are close to the impartial culture assumption). This model enables us to measure in a simple way how the level of correlation in the input rankings impacts our results. In all tests, the number of voters is set to 50 and the ranking $\sigma$ is set arbitrarily as the $k$-wise Kemeny rule is neutral. For each triple $(n, k, \phi)$ considered, the results are averaged over 50 preference profiles.

Practicability of the dynamic programming approach.

We first evaluate our dynamic programming approach on instances with different values for $m$ and $k$. Note that the computational performance measured here is not impacted by the level of correlation in the input rankings as it does

---

3Implementation in C++. All times are CPU seconds on an Intel Core i7-8700 3.20 GHz processor with 16GB of RAM.
not change the number of states in dynamic programming nor the computation time to determine the optimal value in each state. Hence, we only consider instances generated under the impartial culture assumption, i.e., with φ = 1. Table 2 (Rows 3-5) displays the average, max and min running times obtained for some representative (m, k) values. As expected, the running times increase exponentially with m. Conversely, parameter k seems to have a moderate impact on the running times. The dynamic programming approach enables us to solve k-KAP in a time of up to 3 sec. (resp. 76 sec.) for m ≤ 14 (resp. m ≤ 18).

**Influence of k on the set of consensus rankings.** Second, we study the impact of k on the set of optimal solutions to k-KAP. Indeed, one criticism for the Kemeny rule is that there exists instances for which the set of consensus rankings is compounded of many solutions which are quite different from one another. Thus, we investigate if increasing k helps in mitigating this issue. For this purpose, we consider the same instances as before and compute the average number of consensus rankings denoted by |R∗|avg. The results are displayed in the sixth row of Table 2. Interestingly, this measure decreases quickly with k. For instance, when m = 18, |R∗|avg is divided by 5 when k increases from 2 to 9 and is below 2 when k = m. The intuition is that δk becomes more fine-grained as k increases.

**Impact of the 3-wise majority graph.** Lastly, we study the impact of the preprocessing method proposed in Section 4 for k = 3. This preprocessing uses the k-wise majority digraph to divide k-KAP into several subproblems which can be solved separately by dynamic programming. Hopefully, when voters’ preferences are correlated (i.e., for “small” φ values), these subproblems become smaller and more numerous, making the preprocessing more efficient. The results are shown in Table 3, where the results obtained without preprocessing are also given in the last column. The obtained running times are highly dependent on φ. For instance, with m = 18, the average running time for solving 3-KAP is above 1 minute if φ = 0.95 while it is below 1 second if φ ≤ 0.85. This gap is necessarily related to the preprocessing step, since φ has no impact on the running time of the dynamic programming approach. To explain this significant speed-up, we display in Table 4 the average size of the largest SCC of the 3-wise majority digraph at the end of the preprocessing step. Unsurprisingly, this average size turns out to be correlated with φ: when φ ≤ 0.5, the size of the largest SCC is almost always 1. Hence, the preprocessing step is likely to yield directly a consensus ranking. In contrast, when φ = 0.95, the average size of the largest SCC is close to m, thus the impact of the preprocessing is low.

**6 Conclusion**

In this paper, we advocate using the results of setwise contests between candidates to design social welfare functions that are less myopic than those only based on pairwise comparisons. In this direction, we have studied a k-wise generalization of the Kemeny rule, and established that determining a consensus ranking is NP-hard for any k ≥ 3. After proposing a dynamic programming procedure, we have investigated a k-wise variant of the majority graph, from which we developed a preprocessing step. Computing this graph is a polynomial time problem for k = 3 but becomes NP-hard for k ≥ 4. The numerical tests show the practicability of the approach for up to 18 candidates. A natural research direction is to investigate the complexity of determining a consensus ranking for δk when k = m, because our hardness result only holds for fixed values of k. Another avenue to explore is to propose alternative definitions of k-wise majority graphs that are easier to compute for k > 3. Finally, other social welfare functions based on the results of setwise contests are worth investigating in our opinion, both from the axiomatic and the computational points of view.
