Joint Parsing and Generation for Abstractive Summarization

Kaiqiang Song, Logan Lebanoff, Qipeng Guo
Xipeng Qiu, Xiangyang Xue, Chen Li, Dong Yu, Fei Liu

Abstract

Sentences produced by abstractive summarization systems can be ungrammatical and fail to preserve the original meanings, despite being locally fluent. In this paper we propose to remedy this problem by jointly generating a sentence and its syntactic dependency parse while performing abstraction. If generating a word can introduce an erroneous relation to the summary, the behavior must be discouraged. The proposed method thus holds promise for producing grammatical sentences and encouraging the summary to stay true-to-origin. Our contributions of this work are twofold. First, we present a novel neural architecture for abstractive summarization that combines a sequential decoder with a tree-based decoder in a synchronized manner to generate a summary sentence and its syntactic parse. Secondly, we describe a novel human evaluation protocol to assess if, and to what extent, a summary remains true to its original meanings. We evaluate our method on a number of summarization datasets and demonstrate competitive results against strong baselines.

Introduction

It is crucial for a summary to not only condense the source text but also render itself grammatical. Without grammatical sentences, a summary can be ineffective, because human brain derives meaning from the sentence as a whole rather than individual words. Abstractive summarization has made considerable recent progress (See, Liu, and Manning 2017; Chen and Bansal 2018; Kryscinski et al. 2018). Nonetheless, studies suggest that system summaries remain imperfect. A summary sentence can be ungrammatical and fail to convey the intended meaning, despite its local fluency (Song, Zhao, and Liu 2018; Lebanoff et al. 2019a). In Table 1, we show example abstractive summaries produced by neural abstractive summarizers. The first summary has failed to conform to grammar and other summaries changed the original meanings. These summaries not only mislead the reader but also hinder the applicability of summarization techniques in real-world scenarios.

In this paper, we attempt to remedy this problem by introducing a new architecture to jointly generate a summary sentence and its syntactic parse, while performing abstraction.

Table 1: Example summaries generated by neural abstractive summarizers. They are manually re-cased for readability.

This is a non-trivial task, as the method must tightly couple summarization and parsing algorithms, which are two significant branches of NLP. A joint model for generating summary sentences and parse trees can be more appealing than a pipeline method. The latter may suffer from error propagation, e.g., an ill-formed summary sentence can lead to more parsing errors. Further, a joint method mimics the human behavior, e.g., an editor writes a summary and makes corrections instantly as the text is written. She needs not to finish the whole summary in order to correct errors. A method that incrementally produces a summary sentence and its syntactic parse aligns with this observation.

Our proposed joint model seeks to transform the source sequence to a linearized parse tree of the summary sequence. The model seamlessly integrates a shift-reduce dependency parser into a summarization system employing the encoder-decoder architecture. A “SHIFT” operation leads the summarizer to generate a new word by copying it from the source text or choosing a word from the vocabulary; whereas a “REDUCE” operation adds a dependency arc between words of the partial summary. The challenge of this task is to construct effective representations that support both tasks, as they require different contextual representations. We propose to couple a sequential decoder for predicting new summary words and a tree-based decoder for predicting dependency arcs, and ensure both decoders work in a synchronized fashion. We also introduce an important addition making use
of topological sorting of tree nodes to accelerate the training procedure, making the framework computationally feasible. Our research contributions can be summarized as follows:

- we propose to simultaneously decode sentences and their syntactic parses while performing abstraction. Our work represents a first attempt toward joint abstractive summarization and parsing that holds promise for improved sentence grammaticality and truthful summaries;
- we present a novel neural architecture coupling a sequential and a tree decoder to generate summary sentences and parse trees simultaneously. Experiments are performed on a variety of summarization datasets to demonstrate the effectiveness of the proposed method;
- we describe a new human evaluation protocol to assess if an abstractive summary has preserved the original meanings, and importantly, if it has introduced any new meanings that are nonexistent in the original text. The last factor is largely under-investigated in the literature.

**Related Work**

Recent years have seen increasing interest in summarization using encoder-decoder models (Rush, Chopra, and Weston 2015; Nallapati et al. 2016; See, Liu, and Manning 2017; Celikyilmaz et al. 2018; Lebanoff et al. 2019b). An encoder condenses the source text to a fix-length vector and a decoder unrolls it to a summary. An encoder (or decoder) can be realized using recurrent networks (Chen et al. 2016; Tan, Wan, and Xiao 2017; Cohan et al. 2018; Lebanoff, Song, and Liu 2018; Gehrmann, Deng, and Rush 2018), convolutional networks (Chopra, Auli, and Rush 2016; Narayanan, Cohen, and Lapata 2018), or Transformer (Devlin et al. 2018; Liu et al. 2018; Song et al. 2020). To generate a summary word, a decoder can copy a word from the source text or select an unseen word from the vocabulary. This flexibility allows for diverse lexical choices. Nevertheless, with greater flexibility comes the increased risk of producing ill-formed summary sentences that are ungrammatical and fail to preserve the original meanings.

Parsing the source text to identify summary-worthy textual units has been exploited in the past. Marcu (1997; 1998) utilizes discourse structure generated by an RST parser to identify summary units that are central to the claims of the document. A number of recent studies have explored constituency and dependency grammars (Daumé III and Marcu 2002; Clarke and Lapata 2008; Martins and Smith 2009; Filippova 2010; Berg-Kirkpatrick, Gillick, and Klein 2011; Wang et al. 2013; Durrett, Berg-Kirkpatrick, and Klein 2016), rhetorical structure (Christensen et al. 2013; Yoshida et al. 2014; Li, Thadani, and Stent 2016), and abstract meaning representation (Liu et al. 2015; Liao, Lebanoff, and Liu 2018; Hardy and Vlachos 2018) to generate compressive and abstractive summaries. In this paper we emphasize that target-side syntactic analysis is especially important to ensure the well-formedness of abstractive summaries, because generating summary words and predicting relations between words are interleaved operations.

Summarization and parsing are traditionally regarded as separate tasks. These systems are now both realized using neural sequence-to-sequence models, making it possible to tackle both tasks in a single framework. There have been a variety of studies examining neural dependency parsers using transition- and graph-based algorithms (Dyer et al. 2015; Kiperwasser and Goldberg 2016; Dozat and Manning 2017; Ma et al. 2018). Our method, inspired by the recurrent neural network grammar (RNNG; Dyer et al., 2016) that describes a generative probabilistic model for parsing and language modeling (Kuncoro et al. 2017), offers a way to perform summary generation and parsing in a synchronized manner. Incorporating syntax is found to improve translation (Li et al. 2017a; Erguchi, Tsuruoka, and Cho 2017; Wu et al. 2017; Wang et al. 2018). But to date, there has been little work to simultaneously generate a sentence and its syntactic parse, combining summarization with parsing techniques. Our aim is not to improve existing parsers but to leveraging parsing for abstractive summarization. Parsing is essentially a structured prediction problem, whereas summarization involves information reduction from source to target, which poses an important challenge. In the following section, we describe our model in detail.

**Our Approach**

Our goal is to transform a source text $x$ containing one or more sentences to a target sequence containing a linearized parse tree of the summary, represented by $y^T$. We expect a summary to contain a single sentence, as our focus is to improve sentence grammaticality. We use dependency grammar as syntactic representation of the summary. Dependency is useful for semantic tasks and transition-based parsing algorithms are efficient, linear-time in the sequence length.

**Problem formulation**

Our target sequence $y^T$ consists of interleaved $\text{GEN}(w)$ and $\text{REDUCE-L/R}$ operations that incrementally build a dependency parse tree. Table 2 shows an example. The second column contains $y^T$ and the third column contains partial dependency trees stored in a stack. A $\text{GEN}(w)$ operation pushes a summary word $w$ to the stack; $\text{REDUCE-L}$ creates a left arc between the top and second top word in the stack, where the top word is the head; $\text{REDUCE-R}$ creates a right arc where the top word is the dependent. We choose not to label the arcs, as this work focuses on generating well-structured sentences but not on predicting labels. The decoding process comes to an end when there is a single tree remaining in the stack. A summary $y$ can be obtained from $y^T$ by retrieving all GEN operations.

We aim to predict the target sequence $y^T$ conditioned on the source $x$. The process proceeds incrementally. As illustrated in Eq. (1), $P(y^T|x)$ is factorized over time steps.

---

1We make our implementation and models publicly available at https://github.com/ucfnlp/joint-parse-n-summarize

2When a multi-sentence summary is desired, it is possible to generate summary sentences repeatedly from selected subsets of source sentences, as suggested by recent studies (Chen and Bansal 2018; Gehrmann, Deng, and Rush 2018).

3Our method is also general enough to allow other syntactic/semantic formalisms such as the constituency grammar or abstract meaning representation (Banerescu et al. 2013; Konstas et al. 2017) to be exploited in future work.
\(P(y^T = o | y^T_{<t}, x)\) denotes the probability of a parsing operation, where \(o \in \{\text{REDUCE-L, REDUCE-R, GEN}\}\) and GEN is unlexicalized. \(P(y^T = w | y^T_{<t}, x)\) represents the probability of generating a summary word \(w\) at the \(t\)-th step; the word can either be copied from the source text or selected from the vocabulary.

\[
P(y^T | x) = \prod_t \left[ P(y^T = o | y^T_{<t}, x) \right]^{\text{parsing}} \times \left[ P(y^T = w | y^T_{<t}, x) \right]^{\lfloor o = \text{GEN} \rfloor}^{\text{summarization}}
\]

At training time, the ground-truth sequence \(\hat{y}^T\) is available, \(P(\hat{y}^T = w | \hat{y}^T_{<t}, x)\) needs only be computed for certain steps where the parsing operation is GEN, as indicated by \(\lfloor o = \text{GEN} \rfloor\). Our loss term corresponds to the conditional log-likelihood which can be separately calculated for parsing and summarization operations (Eq. (2)). During inference, we calculate \(P(y^T = y | y^T_{<t}, x)\) as a joint distribution over parsing and summarization operations, where \(y^T \in \{\text{REDUCE-L, REDUCE-R, GEN}(w)\}\).

\[
\log P(\hat{y}^T | x) = \sum_t \log P(\hat{y}^T = o | \hat{y}^T_{<t}, x) + \sum_{t:o = \text{GEN}} \log P(\hat{y}^T = w | \hat{y}^T_{<t}, x)
\]

**Neural representations** A crucial next step is to build neural representations to support both tasks. Predicting the next parsing operation requires us to build an effective representation for partial parse trees, denoted by \(h^T_t\), at the \(t\)-th step, whereas predicting the next summary word suggests an effective representation for the partial summary, represented by \(h^T_t\). We envision both tasks to benefit from a context vector \(c^T_t\) that encodes source content that is deemed important for the \(t\)-th decoding step. We next describe a new architecture building representations for \(h^T_t\), \(h^Y_t\), and \(c^T_t\).

We model partial trees using stack-LSTM (Dyer et al. 2015; 2016). Our stack maintains a set of partial trees at any time \(t\); they are shown in the \(t\)-th row of Table 2. For each partial tree, we build a vector representation for it by recursively applying a syntactic composition function (Eq. (3)). The representation is built from bottom up, shown in the dotted circle of Figure 1. A left arc (REDUCE-L) pops two elements from the stack. It then applies the composition function to create a new representation \(g_{\text{new head}}\) and push it onto the stack; similarly for right arc (REDUCE-R). A GEN \((w)\) operation pushes the embedding of a summary word \(e(w)\) to the stack.\(^4\) Kuncoro et al. (2017) report that the composition function learns to compute a tree representation by preserving the semantics of the head word, which fits our task.

\[
g_{\text{new head}} = \tanh(W^g[g_{\text{head}} || g_{\text{dependent}}] + b^g) \quad (3)
\]

We introduce an LSTM, denoted by \(f_{\text{decoder_tree}}\) to consume the partial tree representations of time \(t\) one by one to build hidden representation \(h^T_t\). An illustration is presented in Figure 1. E.g., when \(t=7\), the stack contains 3 partial trees and we build a vector representation for each. \(f_{\text{decoder_tree}}\) is unrolled 3 steps and its last hidden state is \(h^T_7\). Similarly, we build the partial summary representation \(h^Y_7\) using an LSTM denoted by \(f_{\text{decoder_seq}}\), which consumes the embeddings of summary words. For example, when \(t=7\), there are 5 words in the partial summary, \(f_{\text{decoder_seq}}\) is unrolled 5 steps and its last hidden state is used as \(h^Y_7\). Note that for some steps, e.g., \(t=9\), no summary words are generated, we copy \(h^Y_7\) from its previous step \(h^Y_{t-1}\).

A context vector \((c^T_t)\) encoding the source content that is deemed important for the \(t\)-th decoding step is crucial to our method. Important source content can not only aid in the prediction of future summary words but also parsing operations.

---

\(^4\)\(e(w)\) has the same size as partial tree representations \(g\).
We build the context vector $c^x_t$ in two steps. First, we encode the source text $x$ using a two-layer bidirectional LSTM denoted by $f_{encoder}$. We use $\{h^x_i\}$ to denote the encoder hidden states, where $i$ is the index of source words. Next, we characterize the interaction between encoder and decoder hidden states using an attention mechanism (Eq. (4)). We concatenate the partial tree and partial summary representations $[h^y_t || h^x_t]$ to form the decoder state. The score $S_{t,i}$ measures the importance of the $i$-th source word to the $t$-th decoding step. A context vector $c^x_t$ is then constructed as the weighted sum of source representations (Eq. (5)).

$$S_{t,i} = w^t \tanh(W^d[h^y_t || h^x_t] + W^c h^x_t)$$

$$c^x_t = \text{softmax}(S_t)h^x$$

**Prediction** We predict summary words $P(y^T_t = w|y^T_{<t}, x)$ and parsing operations $P(y^O_t = o|y^O_{<t}, x)$ with these representations. We expect historical parsing operations to be helpful for the latter task, i.e., the sequence of $\{\text{REDUCE-L, REDUCE-R, GEN}(w)\}$ operations shown in Table 2. We thus use an LSTM to encode the sequence of past operations and its last hidden state is denoted by $h^O_t$. A parsing operation is predicted based on $[h^y_t || h^O_t || c^x_t]$, and we apply the softmax to obtain a distribution over parsing operations (Eq. (7)).

$$h^T_t = \tanh(W^a[h^y_t || h^O_t || c^x_t] + b^a)$$

$$P(y^T_t = o|y^O_{<t}, x) = \text{softmax}(W^o h^T_t)$$

A summarizer should allow a summary word to be copied from the source text or generated from the vocabulary. We implement a soft switch following See et al. (2017), where $\lambda = \sigma(W^z[h^y_t || h^O_t || c^x_t]) + b^z$ is the likelihood of generating a summary word from the vocabulary. The generation probability is defined in Eqs. (8-9). If a word $w$ occurs once or more times in the source text, its copy probability $\sum_i w_i = w \alpha_{t,i}$ is the sum of its attention scores over all the occurrences, where $\alpha_{t,i} = \text{softmax}(S_t)$. If a word $w$ appears in both the vocabulary and source text, $P(y^O_t = w|s)$ is a weighted sum of the generation and copy probabilities.

$$\tilde{h}^y_t = \tanh(W^z[h^y_t || h^O_t || c^x_t] + b^z)$$

$$\tilde{P}(y^O_t = w|y^O_{<t}, x) = \text{softmax}(W^w \tilde{h}^y_t)$$

$$P(y^O_t = w|s) = \lambda \tilde{P}(y^O_t = w|s) + (1 - \lambda) \sum_i w_i = w \alpha_{t,i}$$

**Acceleration** Obtaining partial tree representations $(h^T_t)$ can be computationally expensive, because $h^T_t$ has to be computed bottom-up according to the topology of a parse tree. Further, parse trees in a mini-batch exhibit distinct topology, making it difficult to execute parallel; frameworks such as DyNet (Neubig et al. 2017) often process one instance at a time. In this work we instead propose to arrange the tree nodes of all instances into groups according to their topological order; representations for nodes of the same group $(h^T_t)$ are computed in parallel. For example, in Figure 1, the nodes marked with “1” are first processed, followed by nodes marked with “2” and so forth. This strategy allows for mini-batch training with parse trees of distinct topology and maximizing the usage of computing resources.

### Experiments

We present our datasets, settings, baselines, qualitative and quantitative evaluation of our proposed method. We then discuss our findings and shed light on future work.

### Data and Hyperparameters

We conduct experiments on a variety of datasets to gauge the effectiveness of our proposed method. We experiment with GIGAWORD (Parker 2011) and NEWSROOM (Grusky, Naaman, and Artzi 2018). GIGAWORD contains about 10M articles gathered from seven news sources (1995-2010); NEWSROOM is a more recent effort containing 1.3M articles (1998-2017) collected from 38 news agencies. We use the standard data splits and follow the same procedure as Rush et al. (2015) to process both datasets. The task of GIGAWORD and NEWSROOM is to reduce the first sentence of a news article to a title-like summary.

The CNN/DM dataset (Hermann et al. 2015) has been extensively studied. We use the version provided by See et al. (2017) but formulate it as a sentence summarization task. We aim to condense a source sentence to a well-formed summary sentence. The source sentences are obtained by pairing each summary sentence with its most similar sentence in the article according to averaged R-1, R-2, and R-L F-scores (Lin 2004). We denote this reduced dataset as “CNN/DM=R.” It is distinct from GIGAWORD and NEWSROOM because its ground-truth summaries are full grammatical sentences, whereas the latter are article titles that appear enticing but not necessarily be full sentences.

We further experiment on many-to-one sentence summarization, where the goal is to fuse multiple source sentences to a summary sentence. Existing datasets for sentence fusion are often small, containing thousands of instances (Thadani and McKeown 2013). In this work we present a novel use of a newly released dataset—WebSplit (Narayan et al. 2017). The dataset was originally developed for sentence simplification, where a lengthy source sentence is to be converted to multiple, simpler sentences for ease of understanding. Importantly, we swap the source and target sequences, so that the task becomes fusing multiple source sentences to a well-formed summary sentence. We name this task WebMERGE to avoid confusion. On average, a source text contains 4.4 sentences and the target is a single sentence. A (source, target) pair is accompanied by a set of semantic triples in the form of “subject|property|object” and the semantics remain unchanged during merging. We utilize these triples for human evaluation (§3). In Table 3, we provide statistics of all datasets used in this study.

Hyperparameters
We create an input vocabulary to contain word appearing 5 times or more in the dataset; the output vocabulary contains the most frequent 10k words. We set all LSTM hidden states to be 256 dimensions. Because datasets containing both summaries and human-annotated dependency parses are unavailable, we use the Stanford parser (Chen and Manning 2014) to obtain parse trees for reference summaries. During training, we use a batch size of 64 and Adam (Kingma and Ba 2015) for parameter optimization, with lr=1e-3, betas=[0.9,0.999], and eps=1e-8. We apply gradient clipping of [-5,5], and a weight decay of 6e-6. At decoding time, we apply beam search with reference (Tan, Wan, and Xiao 2017) to generate summary sequences. K=10 is the beam size.

Experimental Results

Summarization
We present summarization results on all datasets. Evaluation is performed using the automatic metric of ROUGE (Lin 2004), which measures the n-gram overlap between system and reference summaries, as well as human evaluation of grammaticality and preservation of meanings. We discuss our findings at the end.

In Table 4, we present summarization results on the Gigaword test set containing 1951 instances. We are able to test its impact on summarization performance; this corresponds to removing $h_t^r$ and $h_t^{w2}$ in all equations. All other components remain the same. As shown in Table 4, our GenParse system performs on par with or superior to state-of-the-art systems on the standard Gigaword test set. The full model yields the highest R-2 score of 18.85. It outperforms the GenParse-BASE model, demonstrating the effectiveness of coupling a sequential decoder with a tree-based decoder in a synchronized manner.

- **ABS** and **ABS+** (Rush, Chopra, and Weston 2015) are the first work using an encoder-decoder architecture for summarization;
- **Luong-NMT** (Chopra, Auli, and Rush 2016) reimplements the attentive encoder-decoder of Luong et al. (2015);
- **RAS-LSTM** and **RAS-Elman** (Chopra, Auli, and Rush 2016) describe a convolutional attentive encoder that ensures the decoder focuses on appropriate words at each step of generation;
- **ASC+FSC1** (Miao and Blunsom 2016) presents a generative auto-encoding sentence compression model jointly trained on labelled/unlabelled data;
- **lv2k-1sent** and **lv5k-1sent** (Nallapati et al. 2016) address issues in the encoder-decoder model, including modeling keywords, capturing sentence-to-word structure, and handling rare words;
- **Multi-Task w/ Entailment** (Pasunuru and Bansal 2018) combines entailment with summarization in a multi-task setting;
- **DRGD** (Li et al. 2017b) describes a deep recurrent generative decoder learning latent structure of summary sequences via variational inference;
- **Struct+2Way+Word** (Song, Zhao, and Liu 2018) describes a structure infused copy mechanism for sentence summarization;
- **EntailGen+QuesGen** (Guo, Pasunuru, and Bansal 2018) is a multi-task architecture to perform summarization with question generation and entailment generation in one framework.

In Table 5 we present summarization results on the **NEWSROOM**, **CNN/DM-R**, and **WEBMERGE** datasets. The task of WEBMERGE is to fuse multiple source sentences to a well-formed summary sentence while keeping the semantics unchanged; the task of NEWSROOM and CNN/DM-R is sentence summarization, but not document summarization. Because of that, the ROUGE scores presented in Table 5 should not be directly compared with other published results. Instead, we train the pointer-generator networks with coverage mechanism (PointerGen; See et al. 2017), one of the best performing neural abstractive summarizers, on the train split of each dataset, then report results on the test split; we apply a similar process to our GenParse systems. We observe that the GenParse-FULL model consistently outperforms strong baselines across all datasets. The results are outstanding because our system jointly performs summarization and dependency parsing; it involves an increased task complexity than performing summarization only; and our full model is able to excel on this task.

Dependency parsing
We expect dependency relations of a summary to be the same or similar to those of the source text or reference summary in order to preserve the original meanings. Generating a summary word means certain dependency relations are simultaneously added to the summary. For example, in Table 2, generating the word escaped
improve the preservation of dependency relations. To jointly summarize and parse, our system can effectively learn to rank this summary among four peers for grammaticality. We proceed by introducing a novel human evaluation protocol assessing system summaries for grammaticality and preservation of original meanings. A quantitative measure is important because it allows us to compare different systems regarding to what extent their abstractive summaries preserve the original meanings and whether the summaries contain any falsified content that are nonexistent in the original texts. The latter is particularly under-investigated in the past. Our evaluation is made possible by utilizing RDF triples provided in WEB MERGE.

Table 6 illustrates the evaluation process. We present a summary to a group of human judges. They are instructed to rank this summary among four peers for grammaticality. Next, we require the judges to answer a set of binary questions. Q1 How would you rank this summary for grammaticality?
☐ 1st (best) ☐ 2nd ☐ 3rd ☐ 4th (worst)

Q2a Does this summary convey the following meaning?
(Albert B. White | birthYear | 1856)
☐ Yes ☐ No

Q2b Does this summary convey the following meaning?
(Albert B. White | deathPlace | Parkersburg, West Virginia)
☐ Yes ☐ No

Q3 Does this summary convey any additional meanings not covered by the above triples?
☐ Yes ☐ No

Table 6: We present a summary to a group of human judges. They are instructed to assess the summary for grammaticality and preservation of original meanings.

We propose to jointly summarize and parse to improve the quality and objectivity of human evaluation.

Table 7: Human assessment of grammaticality and semantic accuracy of various summaries. Our GenParse-FULL achieves the best results on both aspects among all systems.

Conclusion

We propose to jointly summarize and parse to improve the grammaticality and truthfulness of summaries. We introduce a neural model combining a sequential decoder with a tree-based decoder and ensure both work in a synchronized manner. Experimental results show that our method performs on par with or superior to state-of-the-art systems on standard test sets. It surpasses strong baselines on human evaluation of grammaticality and preservation of meanings.

We perform pairwise comparisons between systems. Results reveal that there is no significant difference between GenParse-BASE and PointerGen. All other differences are statistically significant according to a one-way ANOVA with posthoc Tukey HSD test (p < 0.01).
