On Compiling Away PDDL3 Soft Trajectory Constraints without Using Automata

Francesco Percassi, Alfonso E. Gerevini

Via Branze 38, I-25123 Brescia, Italy

Abstract
We address the problem of propositional planning extended with the class of soft temporally extended goals supported in PDDL3, also called qualitative preferences since IPC-5. Such preferences are useful to characterise plan quality by allowing the user to express certain soft constraints on the state trajectory of the desired solution plans. We propose and evaluate a compilation approach that extends previous work on compiling soft reachability goals and always goals to the full set of PDDL3 qualitative preferences. This approach directly compiles qualitative preferences into propositional planning without using automata to represent the trajectory constraints. Moreover, since no numeric fluent is used, it allows many existing STRIPS planners to immediately address planning with preferences without changing their algorithms or code. An experimental analysis presented in the paper evaluates the performance of state-of-the-art propositional planners using our compilation of qualitative preferences. The results indicate that the proposed approach is highly competitive with respect to current planners that natively support the considered class of preferences, as well as with a recent automata-based compilation approach.

Introduction
Soft state-trajectory constraints are temporally extended goals that in PDDL3 are also called preferences (Gerevini et al. 2009). In planning with preferences, the quality of the solution plans depends on the soft goals and preferences that are satisfied by the plans.

PDDL3 supports an useful set of types of preferences expressed through certain modal operators, and in particular the “qualitative preferences” of types at-end (soft goals), sometime, sometime-before, at-most-once, and sometime-after. One of the competition tracks of IPC-5 was centered on qualitative preferences, and since then several systems addressing this class of planning problems have been developed. Most of these systems represent state-trajectory constraints as automata, that are compiled into the problem operators and states or are handled by the planning algorithm.

In this paper we study propositional planning with qualitative preferences through a compilation approach. In particular, we extend previous work on compiling soft goals (Percassi, Gerevini, and Geffner 2017) and soft always goals (Ceriani and Gerevini 2015) to deal with the full set of PDDL3 qualitative preferences that don’t involve explicit numeric time. Differently from most other systems, our method directly compiles qualitative preferences into propositional planning with action costs without using automata to represent the state-trajectory constraints, and without using numeric fluents, as commonly done in other approaches. Propositional planning with action costs is supported by many powerful planners, and the proposed compilation method allows them to immediately support (through the compiled problems) qualitative preferences with no change to their algorithms and code.

The paper also presents an experimental analysis evaluating the performance of state-of-the-art propositional planners supporting action costs using our compilation of soft state-trajectory constraints. The results indicate that the proposed approach is highly competitive with a state-of-the-art planner that natively supports qualitative preference, as well as with a recent (automata-based) compilation approach.

We start with a brief description of the main related work; then, after the necessary preliminaries, we describe the compilation method in detail; finally, we present the experimental analysis and give the conclusions.

Related Work
The structure of the proposed compilation was inspired by the work of Keyder and Geffner (2009) on compiling soft goals into STRIPS with action costs (in the following denoted with STRIPS+). Keyder and Geffner’s compilation scheme is considerably simpler than ours because it does not consider the different kinds of interference between actions and the types of PDDL3 preferences treated in our compilation.

The most prominent existing planners supporting PDDL3 preferences are HPlan-P (Baier, Bacchus, and McIlraith 2009; Baier and McIlraith 2006), which won the “qualitative preference” track of IPC-5, MIPS-XXL (Edelkamp 2006; Edelkamp, Jabbar, and Naizih 2006) and the more recent LPRPG-P (Coles and Coles 2011) with its variants (Coles and Coles 2013). These planners represent preferences through automata whose states are synchronised with the states generated by the action plans, so that an accepting automaton state corresponds to preference satisfaction. For synchronisation HPlan-P and LPRPG-P use planner-specific
techniques, while MIPS-XXL compiles the automata by modifying the domain operators and adding new ones modelling the automata transitions of the grounded preferences.

Our computation method is very different from the one of MIPS-XXL since, rather than translating automata into new operators, the problem preferences are compiled by only modifying the domain operators, possibly creating multiple variants of them. Moreover, our compiled files only use STRIPS+, while MIPS-XXL also uses numeric fluents.

The compilation of LTL goal formulas by Cresswell and Coddington (2004) and Rintanen (2000) handle hard temporally extended goals, instead of preferences, i.e., every specified temporally extended goal must be satisfied in a valid plan, and hence there is no notion of plan quality referred to the amount of satisfied preferences. Rintanen’s compilation considers only single literals in the formulae (while we deal with arbitrary CNF formulae), and it appears that extending it to handle more general formulae requires substantial new techniques. Bayer and McIlrath (2006) observed that Cresswell and Coddington’s approach suffers exponential blow up problems and is less efficient than HPlan-P.

Other works that are related to ours are the compilation schema in (Ceriani and Gerevini 2015), which however supports only soft goals and always preferences, and the recent schema by Wright, Mattmueller and Nebel (2018) (here abbreviated WMN), which supports a class of soft state-trajectory constraints richer than the PDDL3 qualitative preferences. WMN compiles soft trajectory constraints into conditional effects and state dependent action costs using LTL (De Giacomo, De Masellis, and Montali 2014) and automata. Besides the use of automata, other main differences are the following ones. Our compilation has less additional fluents (at most two for each preference against one for each automaton state in WMN), and WMN use numeric fluents while our compilation avoids them. Both WMN and our compilations introduce additional conditional effects, that in WMN are generated from the automaton transitions without considering the structure (preconditions and effects) of the operator to which they are added, and they are the same for every operator. On the contrary, our compilation exploits the operator structure to generate less conditional effects, each of which with a condition specialized for the particular operator where it is added. This leads to a more compact compiled problem, that hence can be easier to solve for a classical planner.

To help the planner search WMN’s “action penalty compilation” introduces some artificial negative penalties (action costs) in the compilation, which however are supported by few planners. WMN’s “positively shifted costs” technique allows to use only zero and positive costs, but it could loose optimality guarantees since an optimal compiled plan might not correspond to an optimal plan for the original problem.

Preliminaries, Background and Notation

A STRIPS problem is a tuple \( \langle F, I, O, G \rangle \) where \( F \) is a set of fluents, \( I \subseteq F \) and \( G \subseteq F \) are the initial state and goal set, respectively, and \( O \) is a set of actions or operators defined over \( F \) as follows. A STRIPS operator \( o \in O \) is a pair \( \langle \text{Pre}(o), \text{Eff}(o) \rangle \), where \( \text{Pre}(o) \) is a set of positive literals over \( F \) and \( \text{Eff}(o) \) is a set of literals over \( F \). A STRIPS+ problem is a tuple \( \langle F, I, O, G, \mathcal{P}, c, u \rangle \) where:

- \( \{ F, I, O, G, c \} \) is a STRIPS+ problem;
- \( \mathcal{P} = \{ \mathcal{P}_A \cup \mathcal{P}_{SB} \cup \mathcal{P}_{SA} \cup \mathcal{P}_{ST} \cup \mathcal{P}_{AO} \cup \mathcal{P}_G \} \) is the set of the preferences of \( \mathcal{P} \) where \( \mathcal{P}_A \subseteq A, \mathcal{P}_{SB} \subseteq SB, \mathcal{P}_{SA} \subseteq SA, \mathcal{P}_{ST} \subseteq ST, \mathcal{P}_{AO} \subseteq AO, \mathcal{P}_G \subseteq G; \)
- \( u \) is an utility function \( u : \mathcal{P} \rightarrow \mathbb{R}_+^* \).

Figure 1: Semantics of the basic modal operators in PDDL3.

\[(s_0, s_1, \ldots, s_n) \models (\text{at}(\phi)) \text{ if } s_n \models \phi\]
\[(s_0, s_1, \ldots, s_n) \models (\text{always}(\phi)) \]
\[
\text{if } \forall i : 0 \leq i \leq n \cdot s_i \models \phi
\]
\[(s_0, s_1, \ldots, s_n) \models (\text{some}(\phi)) \]
\[
\text{if } \exists i : 0 \leq i \leq n \cdot s_i \models \phi
\]
\[(s_0, s_1, \ldots, s_n) \models (\text{at-most-one}(\phi)) \]
\[
\text{if } \forall i : 0 \leq i \leq n \cdot s_i \models \phi \text{ then } \exists j : j \geq i \cdot \forall k : k \leq j \cdot s_k \models \phi \text{ and } \forall k : k > j \cdot s_k \models \neg \phi
\]
\[(s_0, s_1, \ldots, s_n) \models (\text{some-time-after}(\phi)) \]
\[
\text{if } \forall i : 0 \leq i \leq n \cdot s_i \models \phi \text{ then } \exists j : i < j \leq n \cdot s_j \models \psi
\]
\[(s_0, s_1, \ldots, s_n) \models (\text{some-time-before}(\phi)) \]
\[
\text{if } \forall i : 0 \leq i \leq n \cdot s_i \models \phi \text{ then } \exists j : 0 < j < i \cdot s_j \models \psi
\]
STRIPS+ with preferences will be indicated with STRIPS+P.

Definition 2. Let \( \Pi \) be a STRIPS+P problem with preferences \( \mathcal{P} \). The utility \( u(\pi) \) of a plan \( \pi \) solving \( \Pi \) is the difference between the total amount of utility of the preferences by the plan and its cost: \[
    u(\pi) = \sum_{p \in \mathcal{P}} z(p) u(P) - c(\pi).
\]

The definition of plan utility for STRIPS+P is similar to the one given for STRIPS+ with soft goals by Keyder and Geffner (2009). A plan \( \pi \) with utility \( u(\pi) \) for a STRIPS+P problem is optimal when there is no plan \( \pi' \) such that \( u(\pi') > u(\pi) \). The violation cost of a preference is the value of its utility.

In order to make the presentation of our compilation approach more compact, we introduce some further notation. Given a preference clause \( \phi_i = l_1 \lor l_2 \lor \ldots \lor l_m \) is the equivalent set-based definition of \( \phi_i \) and \( L(\phi_i) = \{ \neg l_1, \neg l_2, \ldots, \neg l_m \} \) is the literal complement set of \( L(\phi_i) \).

Given an operator \( o \) of a STRIPS+P problem, \( Z(o) \) denotes the set of literals \[
    Z(o) = (\text{Pre}(o) \setminus \{ p \mid p \notin \text{Eff}(o)^- \}) \cup \text{Eff}(o)^+ \cup \text{Eff}(o)^-.
\]

Note that the literals in \( Z(o) \) hold in any reachable state resulting from the execution of operator \( o \).

The state where an operator \( o \) is applied is indicated with \( s \) and the state resulting from the application of \( o \) with \( s' \).

Definition 3. Given an operator \( o \) and a CNF formula \( \phi = \phi_1 \land \ldots \land \phi_n \), the set \( C_o(\phi) \) of clauses of \( \phi \) that \( o \) makes certain true in \( s' \) is defined as:
\[
    C_o(\phi) = \{ \phi_i : |L(\phi_i) \cap Z(o)| > 0, \ i \in \{1 \ldots n\} \}.
\]

Given a clause \( \phi_i = l_1 \lor \ldots \lor l_m \) of \( \phi \), condition \( |L(\phi_i) \cap Z(o)| > 0 \) in Definition 3 requires that at least a literal of \( \phi_i \) is in \( Z(o) \), and thus that clause \( \phi_i \) is true in \( s' \).

Definition 4. Given an operator \( o \) and a CNF formula \( \phi = \phi_1 \land \ldots \land \phi_n \), we say that \( o \) can make \( \phi \) true if \( |C_o(\phi)| > 0 \) and, for each clause \( \phi_i \) of \( \phi \) not in \( C_o(\phi) \), \( \overline{T}(\phi_i) \not\subseteq Z(o) \).

The first condition in Definition 4 requires that there is at least a clause of \( \phi \) that is certainly true in \( s' \) independently from \( s \), while the second requires that the clauses that are not certainly true in \( s' \) are not falsified by \( Z(o) \).

Definition 5. Given an operator \( o \) and a CNF formula \( \phi \), we say that \( o \) can make \( \phi \) false in \( s' \) if there is a clause \( \phi_i \) of \( \phi \) such that
1. \( |\overline{T}(\phi_i) \cap Z(o)| > 0 \land \overline{T}(\phi_i) \not\subseteq Z(o) \)
2. \( |L(\phi_i) \cap Z(o)| = 0 \)
3. \( \overline{T}(\phi_i) \not\subseteq \text{Pre}(o) \).

The conditions of Definition 5 require that at least a clause of \( \phi \) (1) has some (but not all) literals which are falsified after the execution of \( o \), (2) has no literal that is certainly true in \( s' \), and (3) is not already false in \( s \).

Operator-Preference Interferences

Operators and preferences may have different kinds of interference, that we have to deal with in their compilation. We say that an operator \( o \) is neutral for a preference \( P \) if its execution in a plan can not affect the satisfaction of \( P \) in the state trajectory of the plan. Otherwise, depending on the preferences type of \( P \), \( o \) can behave as a violator, a threat or a potential support of \( P \). Informally, a violator falsifies the preference, a threat may falsify it (depending on \( s \)), and a potential support may satisfy it over the full state trajectory of the plan. In the following, more formal definitions of these interferences are given for each type of preference.

Operators Affecting Always Preferences

An always preference \( A_\phi \) is violated if \( \phi \) is false in any state on the plan state trajectory. Hence, if \( \phi \) is false in every state \( s' \) generated by an operator \( o \), then \( o \) is a violator of \( A_\phi \).

Definition 6. Given an operator \( o \) and an always preference \( A_\phi \) of a STRIPS+P problem, \( o \) is a violator of \( A_\phi \) if there is a clause \( \phi_i \) of \( \phi \) such that: (1) \( T(\phi_i) \subseteq Z(o) \), and (2) \( \overline{T}(\phi_i) \not\subseteq \text{Pre}(o) \).

Operator \( o \) is a threat of \( A_\phi \) if it is not a violator, its effects make false at least a literal of a clause \( \phi_i \) of \( \phi \), and its preconditions don’t entail \( \neg\phi_i \) (otherwise \( A_\phi \) would be already false in \( s \)). Such clause \( \phi_i \) is a threatened clause of \( A_\phi \).

Definition 7. Given an operator \( o \) and an always preference \( A_\phi \) of a STRIPS+P problem, \( o \) is a threat of \( A_\phi \) if it is not a violator and it can make \( \phi \) false.

The set of clauses of a preference \( A_\phi \) threatened by \( o \) is denoted with \( TC(\phi, o) \).

An operator is neutral for \( A_\phi \) if it makes \( \phi \) true, does not falsify any clause of \( \phi \), or it can be applied only in states where \( \phi \) is false.

Definition 8. Given an operator \( o \) and an always preference \( A_\phi \) of a STRIPS+P problem, \( o \) is neutral for \( A_\phi \) if:

1. for all clauses \( \phi_i \) of \( \phi \), \( |L(\phi_i) \cap Z(o)| > 0 \) or \( |\overline{T}(\phi_i) \cap Z(o)| = 0 \), or
2. there exists a clause \( \phi_i \) of \( \phi \) such that \( \overline{T}(\phi_i) \subseteq \text{Pre}(o) \).

Example. Operator \( o = (\{} \{a \land \neg a\} \) is a threat for \( A_{a \land \neg a} \), a violator of \( A_{a \land \neg a} \), and neutral for \( A_{a \lor \neg a} \) where \( \phi_1 = (b \lor c) \land d \), \( \phi_2 = a \land b \) and \( \phi_3 = d \).

Operators Affecting Sometime Preferences

A sometime preference \( ST_\phi \) is violated if \( \phi \) is never true on the plan state trajectory. Hence, if the state \( s' \) generated by an operator \( o \) makes \( \phi \) true, then \( o \) is a potential support of \( ST_\phi \).

Definition 9. Given an operator \( o \) and a sometime preference \( ST_\phi \) of a STRIPS+P problem, \( o \) is a potential support of \( ST_\phi \) if \( o \) can make true \( \phi \), otherwise the operator is neutral for \( ST_\phi \).

Example. Operator \( o = (\{} \{\neg b\} \) is a potential support of \( ST_{a \lor \neg b} \) where \( \phi_1 = (c \lor \neg b) \land a \) and \( \phi_2 = c \).

Operators Affecting Sometime-before Preferences

A sometime-before preference \( SB_{\phi, \psi} \) is violated if \( \phi \) becomes true before \( \psi \) has been made true on the plan state trajectory. Hence, if operator \( o \) can make \( \psi \) true in \( s' \), then
Given an operator \( o \) and a sometime-before preference \( P = \text{SB}_{o, \psi} \) of a STRIPS+P problem, \( o \) is a potential support of \( P \) if \( o \) can make \( \psi \) true.

If an operator \( o \) can make \( \phi \) true in \( s' \), then \( o \) is a threat of \( \text{SB}_{o, \psi} \). Depending on the state \( s \) where it is applied, such operator can be a violator or neutral for \( \text{SB}_{o, \psi} \).

### Definition 11
Given an operator \( o \) and a sometime-before preference \( P = \text{SB}_{o, \psi} \) of a STRIPS+P problem, \( o \) is a threat of \( P \) if \( o \) can make \( \psi \) true.

### Definition 12
Given an operator \( o \) and a sometime-before preference \( P = \text{SB}_{o, \psi} \) of a STRIPS+P problem, \( o \) is neutral for \( P \) if \( o \) is neither a potential support nor a threat for \( P \).

**Example.** Operator \( o = \{ c \}, \{ \neg a, b \} \) is a potential support of \( \text{SB}_{\phi_1, \psi_1} \), a threat of \( \text{SB}_{\phi_2, \psi_2} \) and an operator neutral for \( \text{SB}_{\phi_3, \psi_3} \) where \( \phi_1 = c, \psi_1 = (a \lor b) \land d, \phi_2 = (c \lor b) \land d, \psi_2 = c, \phi_3 = d \) and \( \psi_3 = e \).

### Operators Affecting At-most-once Preferences
A preference \( \text{AO}_{\phi} \) is violated if \( \phi \) if \( \phi \) becomes true more than once in the state trajectory. Thus, if an operator \( o \) can make \( \phi \) true in \( s' \), then \( o \) is a threat of \( \text{AO}_{\phi} \).

### Definition 13
Given an operator \( o \) and an at-most-once preference \( P = \text{AO}_{\phi} \) of a STRIPS+P problem, \( o \) is a threat of \( P \) if \( o \) can make \( \phi \) true, otherwise \( o \) is neutral for \( \text{AO}_{\phi} \).

**Example.** Operator \( o = \{ c \}, \{ \{ \neg b \} \} \) is a threat of \( \text{AO}_{\phi_1} \) and neutral for \( \text{AO}_{\phi_2} \) where \( \phi_1 = (c \lor \neg b) \land d \) and \( \phi_2 = d \).

### Operators Affecting Sometime-After Preferences
A sometime-after preference \( \text{SA}_{\phi_1, \psi} \) is violated if \( \phi \) if \( \phi \) becomes true in a state without \( \psi \) becoming true in a succeeding state on the plan state trajectory. Hence, if the state \( s' \) generated by an operator \( o \) can make \( \phi \) true, then \( o \) threatens \( \text{SA}_{\phi_1, \psi} \) because \( \psi \) could be false in \( s' \); \( o \) threatens the preference also if \( \psi \) it can make \( \psi \) false, because \( \phi \) could be true in \( s' \).

### Definition 14
Given an operator \( o \) and a sometime-after preference \( P = \text{SA}_{\phi_1, \psi} \) of a STRIPS+P problem, \( o \) is a threat of \( P \) if \( o \) can make \( \phi \) true or \( \psi \) false.

If an operator \( o \) can make \( \psi \) true in \( s' \), then it is a potential support of \( \text{SA}_{\phi_1, \psi} \) because if the preference is temporarily violated in the plan state trajectory up to \( s \), then \( o \) could make it satisfied.

### Definition 15
Given an operator \( o \) and a sometime-after preference \( P = \text{SA}_{\phi_1, \psi} \) of a STRIPS+P problem, \( o \) is a potential support of \( P \) if \( o \) can make \( \psi \) true.

### Definition 16
Given an operator \( o \) and a sometime-after preference \( P = \text{SA}_{\phi_1, \psi} \) of a STRIPS+P problem, \( o \) is neutral for \( P \) if \( o \) is neither a threat nor a potential support of \( P \).

**Example.** Operator \( o = \{ c \}, \{ \neg a, b \} \) is a potential support of \( \text{SA}_{\phi_1, \psi_1} \), a threat of \( \text{SA}_{\phi_2, \psi_2} \) and an operator neutral for \( \text{SA}_{\phi_3, \psi_3} \) and neutral for \( \text{SA}_{\phi_4, \psi_4} \), where \( \phi_1 = c, \psi_1 = \neg a \land c, \phi_2 = \neg a \land c, \psi_2 = c, \phi_3 = d, \psi_3 = b \lor c, \phi_4 = c \) and \( \psi_4 = d \).

### Compilation of Qualitative Preferences
In this section we describing the general compilation scheme of a STRIPS+P II problem. First we compile II into a problem with conditional effects (and possibly also disjunctive preconditions), which can then be compiled away obtaining a STRIPS+ problem equivalent to II, where problem equivalence is defined as in (Keyder and Geffner 2009). We will use \( O_{\text{neutral}} \) to denote the set of the problem operators that are neutral for all preferences, and \( P_{\text{affected}}(o) \) to denote the set of all problem preferences for which \( o \) is not neutral.

Since the compilation of soft goals is the same as in (Keyder and Geffner 2009), we omit its description, and we focus on the other types of preferences. Moreover, we use a pre-processing step to: (a) filter out from \( \mathcal{P} \) all preferences of type \( A \) and \( S \) that are falsified in the initial state and all preferences of type \( ST \) that are satisfied in it; (b) initialize the plan cost as the sum of the costs of the removed unsatisfied preferences.

For a STRIPS+P problem \( II = \{ F, I, O, G, \mathcal{P}, c, u \} \), the compiled problem of II is \( II' = \{ F', I', O', G', c', u \} \) where:

- \( F' = F \cup V \cup S \cup C' \cup \mathcal{C}' \cup \{ \text{normal-mode}, \text{end-mode} \} \)
- \( I' = I \cup \mathcal{C}' \cup V_{ST} \cup V_{SA} \cup S_{AO} \cup \{ \text{normal-mode} \} \)
- \( G' = G \cup C' \)
- \( O' = \{ \text{collect}(P), \text{forgo}(P) \mid P \in \mathcal{P} \} \cup \{ \text{end} \} \cup \{ \text{comp}(o, \mathcal{P}) \mid o \in O \} \)
- \( \text{forgo}(P) = \{ \text{end-mode}, P_{\text{violated}}(P), \{ P', \neg P' \} \} \)
- \( \text{collect}(P) = \{ \text{end-mode}, P_{\text{violated}}(P), \{ P', \neg P' \} \} \)
- \( \text{end} = \{ \text{end-mode}, \text{normal-mode} \} \)
- \( \text{comp}(o, \mathcal{P}) \) is the function translating operator \( o \) according to Definition 17.

- \( c'(o') = \begin{cases} 
    u(P) & \text{if } o' = \text{forgo}(P) \\
    c(o') & \text{if } o' = \text{comp}(o, \mathcal{P}) \\
    0 & \text{otherwise}
  \end{cases} \)

- \( V = \{ P_{\text{violated}} \mid P \in \mathcal{P} \} \)
- \( S = \{ \phi_{\text{seen}} \mid \text{AO}_{\phi} \in \mathcal{P}_{AO} \} \cup \{ \psi_{\text{seen}} \mid \text{SB}_{\phi, \psi} \in \mathcal{P}_{SB} \} \)
- \( S_{AO} = \{ \phi_{\text{seen}} \mid \text{AO}_{\phi} \in \mathcal{P}_{AO} \land I \models \phi \} \)
- \( V_{ST} = \{ P_{\text{violated}} \mid P = ST \phi, I \models \neg \phi \} \)
- \( V_{SA} = \{ P_{\text{violated}} \mid P = \text{SA}_{\phi, \psi}, I \models \phi \land \neg \psi \} \)
- \( C' = \{ P' \mid P \in \mathcal{P} \} \) and \( \mathcal{C}' = \{ \mathcal{C}' \mid P \in \mathcal{P} \} \).

The collect and forgo actions can only appear at the end of the plan. For each preference \( P \) the compilation of II into II' adds a dummy hard goal \( P' \) that is false in the initial state \( I' \); \( P' \) can be achieved either by action collect(\( P \)), that has cost 0 but requires \( P \) to be satisfied, or by action forgo(\( P \)), that has cost equal to the utility of \( P \) and can be performed only if \( P \) is false (\( P_{\text{violated}} \) is true in the goal state). For each \( P \), exactly one of collect(\( P \)) and forgo(\( P \)) appears in the plan.

The \( P_{\text{violated}} \) literals in the compiled initial state \( I' \) are used to consider each \( ST \) and \( SA \) preference that is not satisfied in \( I \) violated until an operator supporting them is inserted into the plan; the \( \phi_{\text{seen}} \) literals in \( I' \) are necessary.
to capture the violation of the corresponding \( AO \) preference when an operator makes the preference formula true for the second time in the state trajectory.

Function \( comp(o, \mathcal{P}) \) transforms an original operator \( o \) into the equivalent compiled operator \( o' \) with an additional precondition forcing it to appear before the \( forgo \) and \( collect \) operators. Regarding the effects of \( o' \), if \( o \in O_{\text{normal}} \), they are the same of \( o \); otherwise, \( comp(o, \mathcal{P}) \) extends the effects of \( o \) in \( o' \) with a set of conditional effects for each preference affected by \( o \). The definition of such additional effects depends on the type of the affected preference, and on how \( o \) interferes with it; this is detailed below.

**Definition 17.** Given an operator \( o \) the corresponding compiled operator is defined using the following function:

\[
Pre(o') = Pre(o) \cup \{ \text{normal-mode} \}
\]

\[
Eff(o') = Eff(o) \cup \bigcup_{P \in Altwand(o)} W(o, P)
\]

where \( W(o, P) \) is the set of conditional effects concerning the affected preference \( P \) (if any).

In the following, \( \phi_i \) denotes a clause of \( \phi \) and \( \psi_i \) a clause of \( \psi \); a set of formulas is interpreted as their conjunction.

### Conditional Effects for \( AO \) Preferences

The conditional effects for a compiled operator affecting a preference \( A_o \) are defined as follows, where \( \overline{A}(o)_{\phi} \) is the literal-complement of the subset of literals in \( L(\phi_i) \) that are not falsified by \( o \), i.e., \( \overline{A}(o)_{\phi} = L(\phi_i) \setminus \{ L(\phi_i) \cap Z(o) \} \).

**Definition 18.** Given a preference \( P = A_o \) and an operator \( o \) affecting it, the conditional effect set \( W(o, P) \) in the compiled version \( o' \) of \( o \) (according to Definition 17) is:

\[
W(o, P) = \begin{cases} 
\{ \text{when} \ (\text{cond}(o, P)) \ (P\text{-violated}) \} & \text{if } o \text{ is a threat of } P \\
\{ \text{when} \ (\top) \ (P\text{-violated}) \} & \text{if } o \text{ is a violator for } P 
\end{cases}
\]

where \( \text{cond}(o, P) = \bigvee_{\phi_i \in TC(o, P)} (l_1 \land \ldots \land l_q) \)

and \( \{ l_1, \ldots, l_q \} = \overline{A}(o)_{\phi}, (\text{TC}(o, P) \text{ is defined above}) \).

For each affected preference \( P = A_o \), \( o' \) has a (conditional) effect \( P\text{-violated} \) with a condition depending on how \( A_o \) is affected; if \( o \) is a violator, then the condition is always true; if \( o \) is a threat, the condition checks that there exists at least a clause of \( \phi \) that is certainly false in \( s' \) – this is the case if there is at least a threatened clause whose literals that are not falsified in \( s' \) are false in \( s \).

**Example.** Consider the operator \( o = \{ \{ b \}, \{ \neg a, e \} \} \) and preference \( A_o \) with \( \phi = (a \lor b) \land (c \lor d \lor e) \). The second clause of \( \phi \) is threatened by \( o \), and \( \text{cond}(o, A_o) = \overline{A}(o)_{\lor \lor d \lor e} = \neg a, \neg e \).

### Conditional Effects for \( ST \) Preferences

The conditional effects for a compiled operator affecting a preference \( ST_o \) are defined as follows.

**Definition 19.** Given a preference \( P = ST_o \) and an operator \( o \) that potentially supports it, the conditional effect set in the compiled version \( o' \) of \( o \) (according to Definition 17) is:

\[
W(o, P) = \{ \text{when} \ (\text{cond}(o, P)) \ (\neg P\text{-violated}) \}
\]

where \( \text{cond}(o, P) = \{ \phi_i \mid \phi_i \notin C\phi(o) \} \).

As described above, for each \( P = ST_o, P\text{-violated} \) holds in the compiled initial state, and a potential support \( o \) of \( P \) makes \( \phi \) true when all clauses of \( \phi \) in \( C\phi(o) \) hold in \( s \), where \( C\phi(o) \) is the set of clauses of \( \phi \) that are certainly true in \( s' \). If this condition holds in \( s \), then \( o \) falsifies \( P\text{-violated} \).

### Conditional Effects for \( SB \) Preferences

The conditional effects for a compiled operator affecting a preference \( SB_{\phi, \psi} \) are defined as follows.

**Definition 20.** Given a preference \( P = SB_{\phi, \psi} \) and an operator \( o \) affecting it, the conditional effect set \( W(o, P) \) in the compiled version \( o' \) of \( o \) (according to Definition 17) is:

\[
W(o, P) = \begin{cases} 
\{ \text{when} \ (\text{cond}_{\phi}(o, P)) \ (\psi\text{-seen}) \} & \text{if } o \text{ is a potential support of } P \\
\{ \text{when} \ (\text{cond}_{\psi}(o, P)) \ (P\text{-violated}) \} & \text{if } o \text{ is a threat of } P 
\end{cases}
\]

where:

- \( \text{cond}_{\phi}(o, P) = \{ \psi_i \mid \psi_i \notin C\psi(o) \} \)
- \( \text{cond}_{\psi}(o, P) = \{ \neg \psi\text{-seen} \} \cup \{ \phi_i \mid \phi_i \notin C\phi(o) \} \).

An operator \( o \) affecting a preference \( P = SB_{\phi, \psi} \) can behave as (a) a potential support of \( P \), (b) a threat of \( P \), or (c) both. These cases are captured by the two conditional effects of \( o' \) in Definition 20.

In case (a), if all clauses that are not certainly true in \( s' \) (i.e., \( \text{cond}_{\phi}(o, P) \)) hold in \( s \), then \( \psi \) is true in \( s' \), and \( o' \) keeps track of this by making \( \psi\text{-seen} \) true. In case (b), if \( \psi \) has never been true in the state-trajectory up to \( s \) and all clauses of \( \phi \) that are not certainly true (i.e., \( \text{cond}_{\psi}(o, P) \)) hold in \( s \), then \( P \) is violated by \( o \) and \( o' \) makes \( P\text{-violated} \) true in \( s' \). In case (c), if the conditions of both conditional effects hold, \( P \) is violated because \( \psi \) is made true simultaneously with \( \phi \).

### Conditional Effects for \( AO \) Preferences

The conditional effects for a compiled operator threatening a preference \( AO_{\phi} \) are defined as follows.

**Definition 21.** Given a preference \( P = AO_{\phi} \) and an operator \( o \) that threatens \( P \), the conditional effect set \( W(o, P) \) in the compiled version \( o' \) of \( o \) (according to Definition 17) is:

\[
W(o, P) = \begin{cases} 
\{ \text{when} \ (\text{cond}_{\phi}(o, P)) \ (\phi\text{-seen}) \} & \text{if } o \text{ is a potential support of } P \\
\{ \text{when} \ (\text{cond}_{\psi}(o, P)) \ (P\text{-violated}) \} & \text{if } o \text{ is a threat of } P 
\end{cases}
\]

where:

- \( \text{cond}_{\phi}(o, P) = \{ \neg \phi\text{-seen} \} \cup \{ \phi_i \mid \phi_i \notin C\phi(o) \} \)
- \( \text{cond}_{\psi}(o, P) = \{ \phi\text{-seen} \} \cup \{ \phi_i \mid \phi_i \notin C\phi(o) \} \cup \{ l_1 \land \ldots \land l_q \mid \{ l_1, \ldots, l_q \} = L(\phi_i) \} \).

If an operator \( o \) affecting \( P = AO_{\phi} \) makes \( \phi \) true for the first time in the state trajectory (i.e., \( \text{cond}_{\phi}(o, P) \) holds in \( s \)), then the first conditional effect of \( o' \) keeps track that \( \phi \) has become true. Otherwise, if (1) \( \phi \) was true in any state before \( s' \), (2) the execution of \( o \) in \( s \) makes \( \phi \) true, and (3) \( \phi \) was false before (i.e., the three condition sets in \( \text{cond}_{\psi}(o, P) \)), then \( o \) violates \( P \) and \( o' \) makes \( P\text{-violated} \) true.
Conditional effects for \( S_A \) Preferences

The conditional effects for a compiled operator affecting a preference \( S_A \phi \) preference are defined as follows.

**Definition 22.** Given a preference \( P = S_A \phi \) and an operator \( o \) that affects \( P \), the conditional effect set \( W(o, P) \) in the compiled version \( o' \) of \( o \) (according to Definition 17) is:

\[
W(o, P) = \begin{cases} 
\{ \text{when (cond}_P(o, P)) \} & \text{(P-violated)} \\
\{ \text{when (cond}_S(o, P)) \} & \text{if } o \text{ is a threat of } P \\
\{ \text{when (cond}_S(o, P)) \} & \text{if } o \text{ is a support of } P
\end{cases}
\]

where:

- \( \text{cond}_P(o, P) = \{ R(o, \phi), R(o, \neg \psi) \} \)
- \( \text{cond}_S(o, P) = \{ R(o, \psi) \} \)
- \( R(o, \phi) = \begin{cases} 
\top & \text{if } \forall \text{ clause } \phi \text{ of } \phi, |Z(o) \cap L(\phi)| > 0, \\
\land_{\phi_i \in C_\phi(o)}(l_1 \lor \ldots \lor l_q) & \text{where } \{l_1, \ldots, l_q\} \\
& \text{is the set of literals of } \phi_i \text{ not falsified by } o \\
& \text{otherwise.}
\end{cases} \)

An operator \( o \) affecting \( P = S_A \phi, \psi \) can behave as (a) a threat of \( P \), (b) a potential support of \( P \), or (c) both. In case (a) the effect condition captures the fact that \( o \) generates a state \( s' \) where \( \phi \) is true and \( \psi \) false, (temporarily) violating \( P \). In (b) the condition captures the fact that \( o \) generates \( s' \) in which \( \psi \) is true, and so \( s' \) cannot violate \( P \). In (c) only one of the two conditional effects can hold in \( s' \) because their conditions are mutually exclusive. Note that \( R(o, \phi) \) is the condition that has to hold in \( s \) to have \( \phi \) true in \( s' \).

**Compilation equivalence**

It can be proved that the original STRIPS+ problem has a solution plan with a certain total cost (sum of its action costs and of the violated preference costs) if and only if the compiled plan has a solution with the same total cost.

**Proposition 1.** Let \( II' \) be the compiled problem with conditional effects of a STRIPS+ problem \( II \). From any plan \( \pi \) solving \( II \) we can derive a plan \( \pi' \) solving \( II' \) and vice versa, such that the total costs of \( \pi \) and \( \pi' \) are the same.

**Proof.** (Sketch). The proof has the same structure of the plan-correspondence proof for Keyder and Gegffner’s compilation of soft goals (Keyder and Gerevini 2009), with \( \pi' = \langle \pi'', \text{end}, \pi''' \rangle \) in which \( \pi''' \) is obtained from \( \pi \) by replacing the original operators with the compiled ones involving conditional effects, and the rest of \( \pi'' \) is defined as in Keyder and Gerevini’s proof (\( \pi'' \) involves only collect and forgo actions). Since the conditional effects in \( \pi'' \) affect only the additional fluents of the compiled problem, all original operator preconditions remain satisfied in the state trajectory of \( \pi'' \). Moreover, by construction of the conditional effects for the compiled operators, it can be proved that in the state where \( \text{end} \) is applied, for each preference \( P, P-\text{violated} \) holds if and only if \( P \) is violated in \( \pi \). Vice versa, from a valid plan \( \pi' \) we can obtain a plan for \( \pi \) by replacing the compiled operators with their original version, and removing \( \text{end} \) and all collect/forgo actions. By construction of the conditional effects in the compiled operators and of \( \pi \) and \( \pi' \), \( \pi \) violates a preference if and only if \( \pi''' \) contains the corresponding forgo action. It follows that \( \pi \) and \( \pi' \) have the same total costs.

**Compilation of Conditional Effects and Violators**

In the literature, there are two main general methods for compiling conditional effects away. In the first method, proposed by Gazen and Knoblock (1997), each plan of the compiled problem preserves the length of the corresponding plan for the original problem, but an exponential number of compiled operators are generated. In the second method, proposed by Nebel (2000), a polynomial number of new operators are generated, but each plans for the compiled problem increases polynomially the length.

In our context, we use Nebel’s method because, depending on the operators’ structure and the input preferences, many conditional effects can be generated, making Gazen and Knoblock’s method impractical. Moreover, Nebel’s method can be optimised for our conditional effects because of their particular structure. Specifically, the effects of our conditional effects concerning different preferences can never conflict, while those referring to the same preference can be resolved in the compilation by imposing a particular order of evaluation for their conditions. This allows us to simplify the compilation by omitting the so-called “copy-operators” of Nebel’s method. Another optimisation concerns the ordering of the set of operator pairs “activating” the conditional effects, which in Nebel’s original compilation is unordered, while in our context they can be ordered as a sort of macro operators. For lack of space, in this paper we don’t give a detailed description of these optimisations, which leads to a revised method for compiling conditional effect away similar to the technique described in (Ceriani and Gerevini 2015) for always constraints, but extended to deal with every class of PDDL3 qualitative preferences.

Another optimization that we implemented is the following one. For a compiled action that is a violator of a preference \( P \), we assign the violation cost of \( P \) to this action, instead of the forgo action for \( P \), that is removed from the compilation together with goal \( P' \) in \( G' \).

**Experimental Analysis**

We implemented the proposed compilation scheme, and we compared the performance (plan quality) of several propositional planners using it and of LPRPG-P, a the state-state-of-the-art system for satisficing planning that “natively” supports PDDL3 preferences. Moreover, we have evaluated the effectiveness of using our compilation for optimal planning with preferences against an alternative recent compilation based on automata.

We used a selection of the best performing planners from IPC8 and IPC9: LAMA (Richter and Westphal 2010), Mercury (Katz and Hoffmann 2014), MIPlan (Núnez, Borrajo, and Linares López 2014), IBAcoP2 (Cenamor, De La Rosa, 1For our benchmarks we observed that LPRPG-P performs better than the other available systems supporting PDDL3 preferences. OPTIC (Benton, Coles, and Coles 2012) and the best variant of LPRPG-P in (Coles and Coles 2013) often gave runtime errors.
and Fernández 2014), Fast Downward Stone Soup 2018 (Seipp and Röger 2018), abbreviated FDSS, and Fast Downward Remix (Seipp 2018), abbreviated FDRemix. In addition, we used a recent version of LAMA, called LAMA_p (h_R), exploiting admissible heuristic h_R for testing soft goals reachability during search (Percassi, Gerevini, and Geffner 2017).

As benchmarks we used all (100) original problems of the qualitative preference track of IPC-5 (Gerevini et al. 2009), which has five domains: Rovers, TPP, Trucks, Openstacks and Storage. The problems in TPP and TPR have no hard goal. In these benchmarks there is no preference of type sometime-after. The propositional planners were run on the compiled problems, while LPRPG-P was run on the original problems. All experiments were conducted on a 2.00GHz Core Intel(R) Xeon(R) CPU E5-2620 machine with CPU-time/memory limits of 30 minutes/8GB, respectively. The average compilation time was from 0.2 to few seconds for all domains except Trucks for which it was 86 seconds.

The compared planners are evaluated using the IPC quality score (introduced in IPC-6). Given a planner p and a planning instance i, if p solves i, the following score is assigned to p: score(p, i) = cost_best(i)/cost(p, i), where cost_best(i) is the cost of the best known solution for i found by any planner, and cost(p, i) is the cost of the best solution found by p, using at most 30 CPU minutes. If p does not find a solution, then score(p, i) = 0. We also consider another metric for plan quality evaluation, that we call α_cost: if planner p solves instance i, we assign the following score to p

α_cost(p, i) = cost(p, i)/cost_best(i) = \sum_{\pi \in P} \frac{\alpha_{\pi}(i)}{\sum_{\pi \in P} \alpha_{\pi}(i)}

where \(\alpha_{\pi}(i)\) is the set of the preferences in i. If for two planners p and p' we have \(\alpha_{cost}(p, i) < \alpha_{cost}(p', i)\), then p performs better than p' for i, and the difference between these metric values quantifies the performance discrepancy. The α-cost is minimum when the plan \(\pi\) found by p for i is (preference-wise) optimal.

Concerning optimal planning, similarly to what done by WMN (Wright, Mattmüller, and Nebel 2018), we tested our scheme using Fast Downward (Helmert 2006) with three admissible heuristics: \(h^{blind}\), assigning zero to goal states and 1 to every other state, \(h^{max}\) (Bonet and Geffner 2001), and \(h^{prob}\) (Haslum et al. 2007). For this analysis we generated a set of benchmarks using the same methodology of WMN. Starting from the IPC-5 problems, we created simpler instances by randomly sampling subsets of the soft trajectory constraints in the original instances: from each original instance, five additional instances are generated, each of which has, respectively, 1%, 5%, 10%, 20% and 40% of the original (grounded) soft trajectory constraints; the hard goals are all unchanged, if they exist. Since the sampled instances used by WMN are not available, we generated, for each sampling percentage (except for 100%), 3 sampled instances and considered the average performance over them.

### Experimental Results

Tables 1 and 2 give the performances of the compared planners in term of IPC quality score aggregated by domain. The results in Table 1 concerns plan quality considering all preferences (i.e., the original plan metrics in these benchmarks), while those in Table 2 concerns plan quality when only the class of preferences indicated in each subtable is considered for the plan metric (using the original violation costs).

The analysis in Table 2 considers a subset of the planners in Table 1. Overall the compilation approach performs better than LPRPG-P, with five planners obtaining better total IPC scores. The comparison considering each preference class separately shows good performance as well for every preference class except for soft goals.

In Rovers, Trucks and Storage each considered planner performs better than, or at least similarly to, LPRPG-P (except for Mercury in Trucks); IbaCoP2 performs particularly well in Rovers, FDRemix in Trucks and LAMA_p (h_R) in Storage. Also MIPlan works well in Trucks, but it is penalized due to its inferior coverage (it solves only 15 instances out of 20). The tested planners from IPC9, FDRemix and FDSS 2018, perform overall better than those from IPC8, and LAMA_p (h_R) is better than everyone else (it improves the performance of LAMA in all the considered domains.

Table 2: IPC scores of a selection of the tested planners whose plans are evaluated considering each kind of preferences separately. "—" means that no preferences of this class are present. The best scores are indicated in bold.
except Rovers, where there is no soft goal and \(h_R\) cannot be exploited by LAMA\(_P(h_R)\).

On the other hand, LPRPG-P performs similarly to LAMA\(_P(h_R)\) in Openstacks and much better than the other planners in TPP. The observed poor performance of the compilation approach in TPP is mainly due to presence of many soft goals. This is not very surprising since, as shown in (Percassi, Gerevini, and Geffner 2017), compiling soft goals through Keyder and Geffner’s method can sometimes give poor planning performance. Indeed Table 2 shows that for soft goals LPRPG-P has higher IPC score than all others planners. We can also observe that, compared to LPRPG-P, the classical planners achieve better results for preferences of classes always, sometime-before and at-most-once; however, this has not a crucial impact of the overall plan quality, because, according to the plan metrics specified in these problems, violating the soft-goals is more costly than violating the other preferences (or equivalently they are more useful to satisfy than the other preferences).

The comparison of the planners’ performance using the \(\alpha_{\text{cost}}\) helps to further understand the behaviour of the planners. For lack of space, we will focus this analysis on two selected domains: Rovers, one of the considered domains where the proposed compilation approach works better, and TPP, the only domain where we observed poor performance compare to LPRPG-P. Figure 2 shows, for each preference class, the planners’ \(\alpha_{\text{cost}}\) values obtained by adding the relative \(\alpha_{\text{cost}}\) for every instance of the two considered benchmark domains. Each level of the stacked histograms represents the aggregated \(\alpha_{\text{cost}}\) restricted to a specific class of preferences, which indicates how much each class of the (violated) preference contributes to the total preference violation cost.

For Rovers, the IPC score gap between the classical planners and LPRPG-P is mainly due to LPRPG-P’s violation of the sometime-before preferences. Regarding other preferences classes, the violation costs in the generated plans are similar except for IBaCoP2. This planner satisfies more sometime-before and sometime preferences than the others planning, and violates more at-most-once preferences, generally obtaining better quality plans.

For TPP, indeed Figure 2 shows that the most important preferences are the soft goals, which are better satisfied by LPRPG-P. The search pruning technique in LAMA\(_P(h_R)\) exploiting \(h_R\) slightly helps LAMA to achieve more soft goals, but not enough to reach the performance of LPRPG-P.

Table 3 gives results about our compilation scheme for optimal planning. For each of the three considered admissible heuristics, the table indicates the percentage of solved problems. The results are compared with those reported in (Wright, Mattmüller, and Nebel 2018) for the “goal action penalty compilation”. Domain Openstacks here is not considered because no one of the considered heuristics solved any instance. Also note that results for TPP are missing for WMN because they are not reported in WMN’s paper.

According to these results, for the considered benchmarks, our compilation approach seems quite preferable, because an higher coverage is obtained in all three considered domains. This is the case even though the machine that we used for our experiments if less powerful (CPU and memory wise) than the one used by WMN, and moreover our CPU-time limit was half of that used by WMN.

**Conclusions**

We have proposed a new compilation schema for solving propositional planning augmented with PDDL3 soft state-trajectory constraints. Our work significantly extends the original approach of Keyder and Geffner that deals only soft goals. The results of an experimental analysis show that, despite the compilation of only soft goals may be less effective than other approaches such as the LPRPG-P planner, for the considered class of soft state-trajectory constraints our compilation is quite competitive with the state-of-the-art. Moreover, since the planning language of the compiled problem is very simple, many available planners can use it.

---

2 A more detailed experimental comparison with WMN’s approach is very difficult because, at the time of writing, WMN’s compiler, compiled files and solution plans are not available.
